INDEX TO VOLUME I FOR 1939.

- A.
 Abbatoir, Belfast public, 1205
 ABDEHBALEN, E.: *Lehrbuch der physiologischen Chemie, in zwei und dreissig Vorlesungen*, rev., 849; *Neuere Ergebnisse auf dem Gebiete der speziellen Biochemie*, rev., 850
 Abdominal emergencies (Sinclair White), 73; correspondence on, 182
 Abdominal hysterectomy, remote results of (Mrs. Stanley Boyd), 335
 Abdominal laceration, extrusion of viscera, operation, recovery (reported by T. W. Bailey), 152; (H. Tener Galbraith), 785
 Abdominal organs, upper, incisions for operations on (Alexander Donn), 652
 Abdominal surgery. *See* Pregnancy
 Abdominal section four times within ten months necessitated by enterospasm (C. W. Dean), 647
 Abdominal surgery (G. J. Guthrie), 1493
 Abdominal wall, laceration of. *See* Abdominal laceration
 Abdominal wall, rupture of (Basil Hall), 1237
 ABEL, R.: *Einfache Hilfsmittel zur Ausführung bakteriologischer Untersuchungen*, rev., 606
 Aberavon, report of medical officer of health, 1275
 Aberdare, medical officer of health for, 813
 Aberdeen, scarlet fever epidemic in, 240; annual conference of Students' Representative Council in, 499
 Aberdeen University. *See* University
 Abfortificant, diachylon as (Edmund Hay), 214; (Arthur J. Hall), 227
 ABRAHAM, PHINEAS, resignation of from Blackfriars Skin Hospital, 426
 Abscess, appendix, unusual case of due to the pneumococcus and *Bacillus coli communis* (Edward Harrison), with opsonic estimations and vaccine treatment by Edward Turton, 1054
 Abscess, hepatic (Lieutenant-Colonel A. J. S. Simpson), 789
 Abscess of liver with anaebic dysentery (Robert Sandby and James Miller), 771
 Abscess, mastoid, complicated atrophic rhinitis (Fred. Stoker), 329
 Abscesses, "light packing" method of treating (F. Rouget), 736
 Abscess of pancreas (Seton Pringle), 278
 Abscess, perianal (Kerr Love), 536
 Abscess of uterine appendages (A. Donald), 1067
 Academy, the Royal, anatomy at, 1196
 Academy, Royal, of Medicine in Ireland, 20, 91, 154, 276, 338, 409, 470, 533, 661, 722, 788, 843, 900, 954, 1008, 1181, 1358, 1417. *Section of Anatomy and Physiology*; 404; reaction time (T. H. Milroy), 404; sterno-clavicular joint (H. M. Johnston), 404; specimens (Professor M'Loughlin), 404; lantern demonstration (Professor Fraser), 404. *Section of Medicine*: 20, 338, 954, 1417; lupus nubilans (W. G. Smith), 20; habit spasm (Dr. Coleman), 20; persistent ductus arteriosus (Dr. Coleman), 20; case of cretinism (Dr. Moorhead), 20; a year of medical hospital work (Dr. Dawson), 338; intracranial tumour (Dr. Drury), 338; poliomyelitis of the conus medullaris (Dr. O'Carroll), 338; gas in the stomach (Dr. Cahill), 954; progressive bulbar paralysis (Drs. O'Carroll and Purser), 1417; hereditary ataxia (Dr. Drury), 1417; idiopathic muscular atrophy (Dr. Drury), 1417; Grocco's triangle (T. G. Moorhead), 1417; haematoporphyria (Dr. Parsons), 954. *Section of Obstetrics*: 91, 470, 788, 1008; intermenstrual pain (R. D. Purefoy), 91; modified instruments (Dr. Ashel), 470; adenocarcinoma of vulva (Dr. Solomons), 470; ruptured extra-uterine pregnancy (Dr. Freeland), 470; double pyosalpinx (Dr. FitzGibbon), 470; radical cure of backward displacement of uterus (Dr. Jellett), 470; fibro-cystic myomatous uterus (Alfred Smith), 788; cyst of Gaertner's duct (Alfred Smith), 788; Rohanda Hospital reports, 788; recurrent haemorrhage (Dr. Purefoy), 1008; *Section of Pathology*: 154, 661, 843, 1181; case of pernicious anaemia (G. R. Parsons), 154; tuberculosis of lungs with tuberculous tumour (Dr. O'Carroll), 155; case of bismuth poisoning (Mr. Gunn), 155; tumour of brain (Dr. Bewley), 661; septic endocarditis starting from congenital pulmonary narrowing (Dr. Bewley), 661; duodenal ulcer (James Little), 661; tumour of brain (James Little), 662; stenosis of tricuspid and mitral orifices (Dr. Coleman), 662; polyserositis (W. L. de C. Wheeler), 843; spleno-medullary leukaemia (Dr. Rowlette), 1181. *Section of State Medicine*: 533; Irish recommendations of the Royal Commission on the Feeble-minded (W. R. Dawson), 533. *Section of Surgery*: 278, 722, 900, 1358; extirpation of bladder (C. Arthur Ball), 278; abscess of pancreas (Seton Pringle), 278; oesophageal diverticulum (William Taylor), 722; suprapubic prostatectomy (L. G. Gunn), 722; a new voice machine (R. H. Woods), 900; hydropneumothorax and appendicitis (E. H. Taylor), 900; Bier's hyperaemic treatment (R. Atkinson Stoney), 1358; post-operative tetanus (Mr. Gunn), 1358
 Accident Insurance. *See* Insurance
 Accident station, colliery. *See* Colliery
 Accident, what is a? 508
 Accidents, compensation for (T. Churton), 1055
 Accidents of practice. *See* Practice
 Accidents to railway servants. *See* Railway
 Accidents to Workmen Congress. *See* Congress
 Accountants, public, 1268
 Acetonaemia (O. T. Kauffmann), 22
 Acetylene in private houses, 1216
 Acid-fast bacilli (F. W. Twort), 703
 Acromegaly (E. Higham Cooper), 466; (Dr. Maguire), 535
 Act, Apothecaries' Hall (Ireland) and Irish universities, 974
 Act, Notification of Births, 72, 115, 820, 1065, 1088; in Dublin, 72; in Darwen, 115; in London, 820; at Liversedge (West Yorkshire), 1088; discussion on (A. J. Sharp), 1065
 Acts, the Children, 853; infant life protection, 853; prevention of cruelty to children and young persons, 853; suffocation of infants, 853; burning, 853; brothels, prostitution, 853; habitual drunkards, 853; juvenile smoking, 853; reformatory and industrial schools, 853; juvenile offenders, 854; alcohol, 854; venereal children, 854; determination of age, 854; application to Scotland and Ireland, 854
 Act, Midwives, 115, 245, 309, 426, 430, 435, 486, 551, 561, 676, 735, 745, 798, 800, 846, 861, 966, 1091, 1137, 1195, 1275, 1395, 1517; Manchester and Salford, 115, 1505; Department Committee on, and general practitioners' interests, 245, 309, 426, 435, 486, 551, 561, 676, 735, 745, 800, 861, 1077, 1137, 1195, 1275; questions in Parliament, 745; difficulties under, 430; at Halifax, 430; in Lancashire, 561; payment of medical men, 798; discussion on the amendment to (opened by Dr. Kaye), 846; position of medical men and, 966; prosecution under, 1517
 Act, Workmen's Compensation, 52, 190, 231, 257, 254, 290, 291, 314, 435, 443, 638, 695, 854, 1213, 1331, 1394, 1458, 1576; sidelights on (leading article), 231; and compulsory operations, 52, 190, 695; workmen's compensation cases, 190, 314, 443, 638, 695, 1576; medical referees and compensation cases, 237, 854; compensation for permanent injury, 254; cardiac strain (James Cee v. Erie Coal Company), 314; ergophobia, 291; amendment to, wanted in Yorkshire, 435; employers' payments for treatment (Suleman v. Owners of 'Ben Lomond', 7), 443; alleged psychical paraplegia (Delaney v. Richardson and Fletcher), 638; serious and permanent injury (Shenton v. Stafford Coal and Iron Company), 1213; claim in respect of ringworm (Millington v. Woodward), 1213; loss of a hand, 1213; termination of an award, 1331; lead poisoning, 1331; injury to an eye, 1331; refusal to undergo an operation, 1394; alleged carbolic acid poisoning, 1394; probable future incapacity, 1394; medical notes should be taken, 1394; chronic bronchitis, 1518, 1576; strained heart, "arising out of the employment," 1576; aortic aneurysm, 1576
 Act, Workmen's Compensation, and medical referees (R. J. Collie), 854
 Act, Workmen's Compensation, from a medico-legal point of view (Arthur S. Morley), 290
 Act, Workmen's Compensation, compensation for accidents (T. Churton), 1065
 Actinomycosis (Theilwall Thomas), 406
 Actinomycosis as a source of infection for man (Sir Robert Boyce), 471

SPECIAL PLATES.

	PAGE		PAGE
Results of Operations for Carcinoma of the Tongue (Henry T. Butlin), facing	1	Syphilis of the Nervous System in the Light of Modern Research (F. W. Mott), facing	456
Effective Treatment of Acute and Subacute Rheumatism (D. B. Lees), facing	148	Anæmic Abscess with Abscess of Liver (Robert Saundby and James Miller) (Two Plates), facing	772, 773
Primitive Muscle Tissue of the Human Heart (Alexander Gibbs), facing	149	Lord Lister, facing	1360
		Biotripsis or Life-Wear (G. Lenthal Cheate), Plate facing	1412
		Radio-activity and Carcinoma (W. S. Lazarus-Barlow), facing	1468

ILLUSTRATIONS IN THE TEXT.

	PAGE		PAGE
Douglas Argyll Robertson	191	Atrophic Rhinitis, complicated by Mastoid Abscess and Extracranial Abscess (Fred. Stoker) (Two Figures)	330
George Eastes	311	Case of Oedema with Resolution by Urinary Crisis (H. D. Rolleston and F. L. Golla) (Chart)	331
Alexander Patterson	441	Medical Aspect of Dentistry (H. Percy Pickerill) (Four Figures)	396
George Edward Walker	572	Open Inhaler for Administration of Ether, Chloroform or Mixture (Harvey Hilliard)	412
David James Hamilton	651	Syphilis of the Nervous System in Light of Modern Research (F. W. Mott) (Thirteen Figures)	459
Thomas Wakley	697	Plate (Eleven Figures)	456
Claudius Galen Wheelhouse	983	Physiology of Female Genital Organs (W. Blair Bell and Pantland Hick) (Sixty-one Figures)	518, 522, 592, 593, 594, 595, 596, 597, 655, 656, 657, 658, 716, 717, 718, 777, 778, 779, 780, 781, 782
Siméon Snell	1031	Natural Cure of Cancer (W. Sampson Handley) (Four Figures)	585, 586, 587
Lord Lister, facing	1360	Potassium Bichromate in Cancer (James Fenwick) (Eight Figures)	589, 590, 591
Just Lucas-Championnière	1427	Avulsion of a Finger (Horace P. Godfrey)	598
Results of Operations for Carcinoma of the Tongue (Henry T. Butlin), Plate facing	1	Cotton-wool Receptacle for Aurists and Rhinologists	606
Restoration of Vision in the Squint (A. Alison Bradburne)	16	Primary Diffuse Pneumococcal Peritonitis (H. Betham Robinson) (Chart)	652
Removal of Large Renal Calculus (H. Brunton Angus)	28	Incisions for Abdominal Operations (Alexander Don)	653
Syringes for Intramuscular Injections	27	Skin Lesions caused by the Millepora (Frederic Wood Jones) (Two Figures)	699
Queen's College, Belfast	37, 38, 39	Mining Accidents (James Robertson)	713
Royal Victoria Hospital, Belfast	39, 40	Combined Tongue Tractor and Chloroform Tube	730
Mater Infirmorum Hospital, Belfast	41	Ophthalmic Vade-mecum	731
Forster Green Hospital for Consumption	41	Anæsthetic Emergency Case	731
Medical Institute, Belfast	42	Lacrimal Cannula	731
Syphilitic Leucoderma and the Pigmentary Syphilide (Sir Jonathan Hutchinson) (Four Figures)	85, 89	Comedo Expressor	731
Diphtheria Larvæ Infection (Stephen M. Laurence)	88	Anæmic Abscess with Abscess of Liver (Robert Saundby and James Miller), Plates facing	772, 773
Map of the County of London	100, 101	Rotary Haemoglobinometer	794
Contusion of Lung Without External Injuries (Ed. Marten Payne)	141	Intussusception containing a Sarcoma (C. Scott Ridout and J. Ford Palmer)	840
Causation of Inrowing Toena and the Location of Gout (G. Arbour Stephens) (Two Figures)	145	Folds in the Anal Canal (J. Bernard Dawson) (Two Figures)	840, 841
Effective Treatment of Acute and Subacute Rheumatism (D. B. Lees), Special Plate facing	148	Radium in Lupus Erythematosus (Geo. Booth) (Two Figures)	841
Primitive Muscle Tissue of the Human Heart (Alexander Gibbs), Special Plate facing 149 and One Figure on	150	Saline Infusion Indicator	851
Percussion Hammer	159	Auto-Gloving Machine	851
Intestinal Anastomosis Forceps	159	Treatment of Infantile Paralysis by Operation (R. P. Rowlands) (Three Figures)	888, 889
Chloroform Tube Terminal for Use with Biting's Bronchoscope	159	Lead Poisoning in Childhood (A. Jefferis Turner)	895
"Forsyth" Sling Pillow	159	Squint Reader	913
Adenomyoma of Uterus (J. Bland-Sutton) (Four Figures)	199, 200	Inguinal Hernia of Uterus (Rushton Parker)	947
Flagellation of Lymphocytes in the Presence of Excitants both Artificial and Cancerous (H. C. Ross and C. J. Macalister)	207	Fracture of the Thigh in the New-born (J. L. T. Isbister)	952
Simple Form of Vaginal Douch Tube	225	Aneurysm of the Heart of Women (Colin M'Dowall)	953
Case of Tubal Pregnancy with Early Operation (Howard F. Varney)	270		
Compress Heater	286		
Human Glanders (Julius M. Bernstein and E. Rock Carling) (Eight Figures)	320, 321, 322, 324		
Anæsthesia in the Human Subject with Known Percentages of Chloroform Vapour (N. H. Alcock) (Nine Figures)	327, 328, 329

An Address

ON

THE RESULTS OF OPERATIONS FOR CARCINOMA OF THE TONGUE,

WITH AN ANALYSIS OF 197 CASES.

DELIVERED BEFORE THE INTERNATIONAL SURGICAL SOCIETY
IN BRUSSELS, SEPTEMBER, 1908.

BY HENRY T. BUTLIN, F.R.C.S., D.C.L.,

CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

[WITH COLOURED PLATE.]

ORDER OF PAPERS.

- I. Preliminary Remarks.
- II. Total Results of 197 Cases.
- III. Causes of Death from Operation.
- IV. Successful Cases.
- V. Comparison of Results of first 98 with second 99 Cases.
- VI. Comparison of 70 Cases in which the Contents of the Anterior Triangle were Removed, with 44 Cases (during the same period of time) in which they were not Removed.
- VII. Should the Operation on the Tongue and Glands be Performed at a Single Sitting?
- VIII. Is there any Advantage in Postponing the Removal of the Glands until they are Enlarged?
- IX. Is the Removal of the Contents of the Anterior Triangle Sufficient as a Routine Procedure?
- X. Is it Necessary to Remove the Glands on Both Sides of the Neck?
- XI. Are there any Cases in which this is Necessary?
- XII. Is it Necessary to Remove the Muscles to their Attachments on the Bones? (Cheate's theory.)
- XIII. Is it Necessary to Remove the Tissues between the Primary Disease and the Glands?
- XIV. Is there any Part of the Tongue from which the Glands are less Liable to become Affected?
- XV. Does Early Diagnosis render the Prognosis of Operation more Favourable?
- XVI. Cancer of the Floor of the Mouth.
- XVII. Operations for Recurrent Disease.

DESCRIPTION OF COLOURED PLATE.

Fig. 1.—From a doctor, aged 30 (Dr. H. D.). Old areas of leucoplakin on the fore-part of the border of the tongue. Excoriated, very slightly raised area further back, red and glossy, looking just as if it had been rubbed sore by a rough tooth. Has had ulceration here for some time, but the place only became a little harder a fortnight before I saw it. Examined by the Imperial Cancer Research. (March, 1905.)

Fig. 2.—From a man, 70 years of age. Old leucoplakin, with a slightly raised, glazed, and granular epithelioma of short duration. Examined by the Imperial Cancer Research. Mr. F. (July, 1907.)

Fig. 3.—From a man, 60 years of age. Leucoplakin, with a red, smooth, circumscribed plaque, with a slight depression in the centre. It felt quite thin, like a little piece of parchment in the mucous membrane. It had only been noticed four or five weeks. On removal it was found to be almost $\frac{1}{16}$ in. thick, much more than had been suspected. And, on microscopical examination, it had infiltrated the muscles far below its apparent limit. Examined by the Imperial Cancer Research. Mr. A. (December, 1905.)

3

I.

I BELIEVE that the following cases comprise all those in which I have operated for carcinoma of the tongue. The first operation was performed in 1881, and the last a few months ago (June, 1908).

In the year 1895 I first performed a planned operation for the removal of the contents of the anterior triangle of the neck, which was founded on the experience which I had gained from observation of the places in the neck in which the glands are most liable to be diseased. Since that time 70 patients have submitted to that operation. In 44 other patients it has not been performed for various reasons, chiefly on account of the difficulty of inducing the patients to submit to it.

The operations on the tongue have been performed almost entirely through the mouth, and the lower jaw has never been divided, although portions of it have been removed in a number of cases. The object of the operation has been to remove the disease together with, if possible, about three-quarters of an inch of surrounding healthy tissues.

At the commencement of the year 1900, I began to perform a preliminary laryngotomy before proceeding to the removal of the disease of the tongue. This operation has been performed in all cases since that time, amounting in number to between sixty and seventy. It is highly to be recommended, for it has all the advantages of tracheotomy without the disadvantages. It can be performed in less than one minute. It enables the operator to deal much more deliberately and effectually with the disease of the tongue, however extensive this may be, and it enables the anaesthetist to pursue his duties without interruption.

The patients have been traced with great care, but the information which has been obtained respecting the further history of some of them is naturally defective. Thus, it has not always been possible to determine whether recurrence took place in the tongue or in the glands, or the exact relation which the recurrence bore to the disease which was removed. Even with these defects the results are very interesting, and I have tried to answer a number of questions by a careful analysis of them. The answers to some of the questions must not be regarded as final. Further experience may prove that they require

Fig. 4.—From a man, 60 years of age (Colonel L.). A white granular area of leucoplakin of many years' duration, which has recently become malignant. There is no ulceration or excoriation, but the plaque is harder than usual. Examined by the Imperial Cancer Research. The cancer cells were already beginning to pass down between the muscular fibres. (June, 1906.)

Fig. 5.—From a man, aged 49 (Mr. C.). Old thin leucoplakin and chronic superficial glossitis, with one slightly raised spot, red like a pimple. This was suspected to be epithelioma, and was examined by the Imperial Cancer Research. Dr. Bashford could not be sure whether it was or was not an epithelioma. (February, 1907.)

Fig. 6.—From a man, aged 40 (Mr. F.). Small raised, very firm tumour, very fixed in the surface of the tongue. The surface of the tongue was otherwise perfectly natural everywhere. Of about three months' duration. Not red, glazed, excoriated or ulcerated. Very slightly rounded on the surface, otherwise like the top of an almost flat button. Not granular or warty. About the same colour as the surface of the tongue, so that I did not at first notice it. On section, dense white, cutting like gristle, not looking like epithelioma, but more like fibrous tissue. Very circumscribed against the muscle beneath. Examined by the Imperial Cancer Research and by Dr. Goldmann of Freiburg. (February, 1908.)

[2505]

modification. But, for the present, they may be taken as representing very truthfully my own views of the surgery of carcinoma of the tongue.

With regard to the cases themselves, it must be understood that there has been no selection. Operation has been performed during the entire period of twenty-seven years on every patient who was deemed likely to be relieved by it, whether in hospital or private practice. Thus, while it has been my good fortune to operate on some very favourable cases, it has also been my misfortune to be called on to operate on a number of cases which proved to be quite hopeless. On the whole my cases were probably no better and no worse than those which fall to the lot of every surgeon who is engaged pretty largely in this kind of practice. Although, naturally, most of the very bad cases have been failures, a sufficient number of them have been successes to encourage operators not to decline to operate on them. I have been astonished at the success which has attended resolute surgery in some of those in which the result seemed to be hopeless.

But the future of the operative surgery of carcinoma of the tongue undoubtedly lies in *early diagnosis* of the disease and in the *routine removal of the glands* before they are obviously enlarged.

II.

Results of 197 Cases of Cancer of the Tongue operated on by Mr. Butlin in Private and Hospital Practice between the Year 1881 and the present Year (June, 1905).

Year of operation ...	20
Lost sight of after operation ...	1
Died of recurrence in the mouth ...	26
Died of affection of glands without recurrence in the mouth ...	29
Died of recurrence in the glands without recurrence in the mouth ...	10
Died of recurrence in mouth and glands ...	7
Died of recurrence, uncertain whether in mouth or neck or both ...	10
Died of affection of the glands, uncertain whether recurrence in the mouth ...	5
Died of recurrence in the glands, uncertain whether recurrence in the mouth ...	1
Died of affection of glands on other side of neck ...	2
Died of secondary disease of lungs ...	2
Died of cancer of the opposite border of tongue	2
Palliative operations (glands too advanced for removal; cancer of tongue only removed) ...	3
Operation on tongue abandoned ...	4
Operation on glands abandoned ...	1
Cases not countable (operations performed within three years; the patients either died of other diseases within three years or are still alive and well within three years) ...	22
Successful (all these patients lived for from three to twenty-two years free from recurrence; most of them are still alive and well) ...	55

Total ... 197

III.

Causes of Death from Operation.

Died suddenly during the operation ...	7
Sepsis of wound ...	1
Septic pneumonia ...	10
Subsequent hæmorrhage ...	2
Shock ...	2
Asphyxiation (sudden, a week after operation)	1
Heart-failure (some days after light operation in feeble patient, aged 77 years) ...	1
Acute mania (wound doing well) ...	1

Total ... 20

One of the patients who died of hæmorrhage was "a bleeder," and was acquainted with the fact, but concealed it as he wished to have the operation performed.

IV.

Successful Cases: Fifty-five Persons, whose Cases were traced for more than Three Years after the last Operation on Tongue or Glands.

VI.

In the year 1895 I began the routine removal of the contents of the anterior triangle. Out of 114 cases since that time, I removed the contents of the anterior triangle in 70, and did not remove them in 44 cases.

Analysis of the Forty-four Cases in which the Contents of the Anterior Triangle were not removed.

(To these should be added 8 cases in which the patients returned at a later period for removal of enlarged glands, which were not intended to be removed when the tongue was treated, making a total of 52 cases.)

Died of operation ...	6
Died of recurrence in the mouth (in 3 of these the operation was abandoned) ...	7
Died of affection of glands (in 5 of these the glands were enlarged at the time of operation on the tongue, but were not removed for various reasons) ...	15
Died of cancer of opposite border of tongue ...	1
Cases not countable ...	3
Successful cases ...	12

Total ... 44

Eight Cases in which the Glands were Removed at a Later Period because they became Enlarged.

(These cases are also included in the 70 cases of removal of the anterior triangle.)

Recurrence, uncertain where	2
Recurrence in the glands	1
Lost sight of after operation	1
Died of other disease within three years	1
Successful	3
Total	8

Six patients who died of the operation must be deducted from the total of 52 patients, leaving 46 patients. The glands are known to have become enlarged at a later period in 10 + 8 = 18. In addition, they were enlarged at the time of operation on the tongue in 5 other cases, but were not removed. And there are 3 cases (not countable) in which they may still become enlarged.

The percentage of successful cases out of the 44 patients for whom the glands were not removed is as 12 to 41 (for the three not-countable cases must be deducted from the total of 44) = 29.26 per cent.

The causes of death from the operation were:

Acute mania	1
Haemorrhage (in one old man occurred on the night of the operation and proved fatal; in the other case proved fatal nine days after a very severe operation on the floor of the mouth and posterior part of the tongue)	2
Heart failure (when the wound was nearly healed, in a very feeble, gouty subject, 71 years old)	1
Sepsis and anterior mediastinitis	1
Septic pneumonia	1
Total	6

Analysis of the Seventy Cases in which the Contents of the Anterior Triangle were Removed.

Died of the operation	6
Lost sight of after operation	1
Died of recurrence in the mouth	9
Died of recurrence, uncertain where (in one of these the glands could not be entirely removed; operation abandoned)	7
Died of recurrence in the glands (in one of these the submaxillary salivary gland was left and the disease recurred beneath it; in the other 7 cases the glands were enlarged at the time of their removal, and in 5 of these they were demonstrably cancerous)	8
Died of cancer on the opposite side of the tongue	1
Died of affection of glands on opposite side of neck	2
Died of other disease within three years	1
Cases not countable	11
Successful cases	24
Total	70

The successful cases are calculated on the 70 cases, after deducting cases not countable (11), the patient who died within three years of another disease (1), and the patient who was not traced after the operation (1), leaving 57 cases, with 24 successful cases = 42.01 per cent.

The age of the patients operated on showed that 10 of them were over 65 years of age, and 1 over 70 years (77).

The causes of death from the operation were:

Haemorrhage, etc. (both from mouth and neck in a badly alcoholic patient)	1
Suffocation from the sudden falling back of the root of the tongue some days after operation	1
Septic pneumonia	4
Total	6

VII.

Should the Operation on the Tongue and the Removal of the Glands be Performed at a Single Sitting?

The 70 cases in which the contents of the anterior triangle were removed may be tabulated as follows:

Single sitting:			
Glands enlarged	12
Glands not enlarged	10
Total	22
with 4 deaths due to the operation			

Separate sitting (shortly before or after operation on the tongue):

Glands enlarged	15
Glands not enlarged	22
At a later period:			
Glands enlarged	8
Glands not enlarged	2
Total	43

with 2 deaths due to the operation.

Total of the last two groups 48, with 2 deaths due to the operation. In one of these cases the operation on the glands was undertaken twelve days after the operation on the tongue, and a further portion of the tongue was cut out because I feared I had not removed sufficient at the first operation. This further portion was in the floor of the mouth, and the entire wound in the neck became septic.

It will be noticed that the glands were already enlarged in 12 of the 22 cases in which the two operations were performed at a single sitting, and this was one of the reasons why the operation on the glands was not deferred.

It will also be noticed that in 8 of the 10 cases in which the glands were removed at a later period they were enlarged. Indeed, the patients would not have submitted to the operation had the glands not been enlarged. In spite of this, all these 8 patients recovered from the operation, and in 3 out of the 8 the operation was followed by complete success. The following paper, however, shows that such success must be regarded as exceptional.

VIII.

Is there any Advantage in Postponing the Operation on the Glands until they are Enlarged?

For the consideration of this question, 56 cases, in which the results are known, may be used.

Glands enlarged at the time of operation, 34:

Died of recurrence in the neck	7
Successful	11
Glands not enlarged at the time of operation, 22:			
Died of recurrence in the neck	1
Successful	15

It will be seen that the evidence is largely in favour of not deferring the operation until the glands are enlarged.

In the single case of recurrence in the neck in the second series, the submaxillary salivary gland was not removed, but was raised up for the removal of the glands beneath it. Recurrence took place in the lower part of the salivary gland, presumably due to affection of a lymphatic gland which had been overlooked.

In the first series of 34 cases the glands were not obviously cancerous in the large majority of the cases, but they were so in some of the cases. Nevertheless, some of these patients were cured by removal of the cancerous glands, and remained well after many years. One case is especially worth recording in this respect. On June 8th, 1903, the right half of the tongue was removed from a gentleman, aged 56. At the same time the contents of the anterior triangle were dissected out. But a mass of glands beneath the great vessels was so fixed and the patient was so exhausted by the operation, that it was deemed inexpedient to persist in the attempt to remove them. On June 18th I summoned up my courage and again attacked the fixed glands, which were removed with considerable difficulty. The family doctor wrote me in April of this year (1908) to say that his patient is in perfect health, and has not had recurrence either in the tongue or in the glands.

If the operation were restricted, as it used to be, to the removal of glands which are obviously enlarged, the suggestion to defer the operation until the glands are enlarged would have some weight. But as the methodical removal of the contents of the anterior triangle is not restricted to the removal of the glands, but is extended to the removal of the tissues in which the glands are known to lie, the suggestion should not be accepted.

* This suggestion is made in a well-known English work on *Surgical Treatment*, dated 1902.

IX.

Is the Removal of the Contents of the Anterior Triangle sufficient as a Routine Procedure? Or, ought the Contents of the Posterior Triangle on the Same Side also to be Removed?

In my 70 cases there were very few in which the dissection was carried to the extent of removing the contents of the posterior triangle or of dividing the sterno-cleido-mastoides. Yet there were only 8 cases in which the disease was noted to have recurred only in the neck.

In one of these the recurrence took place owing to the omission to remove the submaxillary salivary gland. And in the other 7 cases the glands were enlarged at the time of the operation; in 5 of the 7 they were macroscopically and microscopically cancerous.

I would recommend that the dissection should be carried into the posterior triangle in those cases in which the primary disease is seated far back on the border of the tongue; and in those cases in which the glands are badly affected in the parotid (upper carotid) region.

I would further advise that the dissection should always be carried well up to remove the glands in the parotid region. For this purpose it is necessary to remove the lower part of the parotid salivary gland. In one of my early cases of removal of the anterior triangle the patient died of the operation. At the autopsy an enlarged gland was found in this situation, which had not been removed at the operation.

X.

Is it Necessary to Remove the Glands on Both Sides of the Neck?

The cases of which I have notes are not sufficient in number for the decision of this question. There may have been other cases, among those of which the further history is imperfect, in which the glands were affected on both sides of the neck. So far as the records go, they do not favour the view of the necessity of subjecting every patient to the removal of the glands on both sides of the neck. They are as follows:

Cases in which the glands were affected on both sides of the neck ... 9

In 6 of these 9 cases both sides of the tongue were affected by the primary disease.

In the other 3 cases the primary disease was of one border of the tongue, and, in 1 of the 3, was some distance from the tip.

Cases in which the glands were affected only on the side opposite to the disease ... 5

In 1 of the 3 the primary disease was near the tip, and in another of the 3 it was about 1 in. from the tip. In both those cases the glands were removed from the opposite side of the neck only, and those 2 patients are alive and well many years after the operation.

Cases in which the glands on the opposite side of the neck became diseased after successful removal of the primary disease and the glands on the same side... 2

In both these cases the primary disease was situated on the border of the tongue, and was of rather small extent. It was some distance back on the border in both cases. It showed microscopic signs of excessive malignancy in one of the cases.

XI.

If it is not Necessary to Remove the Glands on Both Sides of the Neck in every Instance, are there Cases in which this Procedure is Desirable?

The following conditions appear to me to call for wider removal of glands:

(i) Those cases in which the glands on both sides of the neck are enlarged.

(ii) Those cases in which the glands are affected only on the side of the neck opposite to the disease.

(iii) Those cases in which the disease is seated on both sides of the tongue, or in which it reaches to the middle line of the tongue.

(iv) Probably it ought to be done in those cases in which microscopical examination gives reason to believe that, although the primary disease is apparently only of

small extent and depth, it is much more malignant than usual; when, for instance, columns of cancer cells are found running deeply down between the muscular fibres.

XII.

Is it Necessary in all Cases to Remove the Muscles to their Attachments?

(During the last two or three years researches on the spread of cancer of the tongue have been made by Mr. Lenthal Cheate, C.B. He has found, in microscopic sections of the muscles at a considerable distance from the primary disease, columns of cancer cells lying between the fibres of muscles, which look quite healthy to the naked eye. He therefore recommends that, according to the seat of the primary disease, the genio-hyoglossus and inferior lingualis or the hyoglossus or the stylo-glossus muscle should be removed back to its attachment to the bone. In cases of cancer of the anterior part of the tongue and the tip, the genio-hyoid muscle and the fascia covering it should be removed. If the primary disease is so situated as to extend into both halves of the tongue, some or all of these muscles should be removed on both sides. As the result of his researches Mr. Cheate is of opinion that the hyoglossus and genio-hyoglossus and inferior lingualis muscles should be removed in every case of cancer of one half of the tongue, even if the primary disease is quite small and in an early stage of its existence.)

Out of the 197 cases there were 99 in which there was no recurrence in the tongue. They are classified as follows:

Died of affection of the glands	39
Died of affection of the glands on the other side of the neck	2
Died of cancer of the lungs	1
Died of cancer of the other border of the tongue	2
Successful	55
Total	99

In addition to these 99 cases there are a number of other cases which cannot be counted because less than three years have elapsed since the operation. But as from two to three years have elapsed in many of them there is now no reason to apprehend recurrence *in situ*.

On the other hand there were 33 cases in which the disease is known to have recurred in the mouth. Most of them are noted as bad or extensive cases; in seven of them the floor of the mouth was affected to a greater or less extent; and in only three of them was the disease of such small extent that I felt afterwards that it would not have recurred in the mouth if it had been more widely removed.

Although these figures do not support Mr. Cheate's suggestion, I think it will be desirable to carry it into effect in the more advanced cases, especially in those in which the disease lies beneath the border of the tongue and passes into the floor of the mouth.

The objections to it in addition to the larger operation which it involves, are that the mobility of the tongue has been, in those few cases in which I have practised it, seriously impaired, and in consequence speech and mastication have not been nearly so good as in those cases in which the disease has been merely cut out without reference to the complete removal of individual muscles.

XIII.

Is it Necessary to Remove the Tissues between the Primary Disease and the Glands?

Although I cannot answer this question decidedly in the negative, the evidence in favour of this course is not, in my opinion, strong enough to justify the extra risk involved. For, in order to carry it out methodically and completely, it would be necessary to remove the primary disease and the glands in one continuous mass. In all but a few cases, the large wound in the neck, in which the great vessels and nerves are exposed, would suppurate, in most cases badly. The risk to life would therefore be very largely increased, and should not be incurred unless a very decided advantage can be claimed for the procedure.

Out of 70 cases in which the anterior triangle was completely cleared out, and a number of other cases in which glands were simply dissected out because they

were enlarged, I have very rarely removed the primary disease and the glands in one continuous mass. Yet 29 of these cases proved to be successful. And out of a large number of the unsuccessful cases, in which recurrence took place either in the mouth alone or in the mouth and neck, and in which the seat of the recurrence was noted, there are only two in which it could reasonably have been attributed to affection of the tissues which were left behind between the primary disease and the glands.

XIV.

Is there any Part of the Tongue from which the Glands are less liable to become Affected?

In 23 cases out of the entire series of 197 only the primary disease was removed, but the patients remained free from recurrence *in situ* and from affection of the glands (successful cases).

The seat of the disease, roughly noted, was as follows:

Dorsum:					
Anterior	8
Further back	2
Border:					
Near the tip	1
At various points	4
Beneath the border	7
Tip:					
Under surface	1
Total	23

For comparison with these cases, I have taken 23 cases (between the 87th and the 197th) in which the glands were not removed, but became affected at a later period:

Dorsum:					
Anterior	4
Border:					
Near the tip	5
At various points	9
Beneath the border	2
Prænum	2
Extensive disease	1
Total	23

In addition to the case which is classed as extensive, because its point of origin was not ascertained, there were several cases in both series in which the disease of the tongue was extensive, but it was possible to determine the point at which it had first appeared.

Perhaps the anterior part of the dorsum is the least dangerous seat of cancer, *quæ* affection of glands. But the results of the second series of cases show that it would not be safe to rely on a special immunity of that part in practice. In one of the cases the primary disease was of quite small size, and had only been noticed a short time.

XV.

Does Early Diagnosis render the Prognosis of Operation more Favourable?

Very small and, presumably, recent cancers were removed in 18 of my cases. They were seated in different parts of the tongue, so that no conclusion can be drawn with reference to the seat of the disease. The results were as follows:

Recurrence <i>in situ</i>	2
Died some years later of cancer of the opposite border of the tongue	2
Died of affection of glands without recurrence <i>in situ</i>	6
Successful (glands removed)	2
Successful (glands not removed)	6
Total	18

It will be seen that the percentage of successes, 8 in 18, was 43.33. And, in 6 of these cases, the operation was restricted to removal of the primary disease.

On the other hand, no fewer than 6 of the patients died at a later period of affection of the glands without recurrence in the tongue. This furnishes very strong evidence of the necessity of removing the glands even in cases of quite small and recent cancer of the tongue.

With regard to the 2 cases of recurrence *in situ*, 1 of them occurred many years ago, and the operation was not as wide as I have been in the habit of practising since that time (largely on account of the failure which followed this particular operation). In the other case there is reason to

believe the cancer was much more virulent than usual, for the operation which was practised would have sufficed for any but a virulent case.

XVI.

Cancer of the Floor of the Mouth.

An impression generally prevails among surgeons that cancer which originates in the floor of the mouth is peculiarly dangerous to life.

The following facts may serve to correct this impression, which I formerly held in common with my surgical colleagues:

No. of cases occurring in my practice, 9:

Died of recurrence in the mouth	4
Died of affection of the glands without recurrence in the mouth	1
Successful	4
Total	9

In all the 5 unsuccessful cases the disease was seated at or close to the frænum linguæ, and in 3 of them had invaded the bone, so that a portion of the jaw had to be removed. These cases were, therefore, peculiarly unfavourable for operation.

In 3 of the 4 successful cases the disease was also situated at the frænum, but it was not adherent to the bone. In 2 of these cases the glands were removed shortly after the operation on the floor of the mouth. These 2 patients are both well at the present time, three years after the operation. In the third case the glands were not removed, and the patient remains well ten years after the operation. In the fourth case the cancer was of very small size, seated beneath the front of the tongue, where it joins the floor of the mouth. It was freely removed, but the glands were not dissected out. That patient is still alive and well, at the age of 79, twenty-two years after the operation.

From these facts it may fairly be assumed that cancer originating in the floor of the mouth can be removed with a good prospect of success, provided it is not very extensive and has not involved the bone. But the two cases in which the operation was successful, although it was limited to the removal of the disease in the mouth, must not be taken to encourage operators to refrain from removing the glands. In most of the cases they were either affected at the time of the operation or became affected with the recurrence of the disease in the mouth.

XVII.

Operations for Recurrent Disease.

Tongue.—Only in five instances has there been an operation for recurrence of the disease in the tongue, and in one of these the disease was not truly recurrent. In 1890 the right border of the tongue was removed for epithelioma. The patient was a very free liver, drank and smoked a great deal. In 1900 some white plaques were removed from the same border of the tongue, but no cancer was found in them. In 1905 (fifteen years after the first operation), he had an epithelioma of the same border, with enlargement of the glands. An attempt was made to remove the disease by one of my colleagues, but the operation was not successful and the patient died in June, 1906.

All these operations for recurrent disease in the tongue were performed in the first 70 cases, 4 of them in the first 30 cases. The disease was not as thoroughly removed as in the cases during the last fifteen or more years. Not one of these lives was saved by the second operation. Two of the 4 patients died of recurrence in the tongue; the other 2 died of affection of the glands, which had been imperfectly removed in both cases.

Glands.—Eight patients were operated on for recurrence in the glands. Again, it is noticeable that 7 of these cases occurred in the first 90 cases, and only 1 in the remaining 107; in that case the submaxillary salivary gland was left for cosmetic purposes, with disastrous result.

The lives of 2 of these 8 patients were saved. The first was an old man, from whom the anterior part of the tongue and some enlarged glands were removed in September, 1893. In May, 1894, two glands were enlarged at the angle of the jaw, and were removed. He came to see me

in 1902—eight years after the second operation—very well, but very feeble from old age.

The second of these patients was a woman from whom one side of the tongue was removed in October, 1894. In December of the same year two or three enlarged glands were removed, and in the following February (1895) some more glands. She remains quite well up to the present time—a period of more than thirteen years.

The results of operations for the removal of recurrent disease, whether of the tongue or glands, have been so bad that operators are counselled to make the first operation as complete as possible, in the belief that the only hope of the patient lies in the thorough manner in which this operation is performed.

THE OPERATIVE TREATMENT OF INTRAORAL CANCER:

WITH SPECIAL REFERENCE TO THE CHOICE OF
OPERATION, ORDER OF OPERATION, AND
LIGATURE OF THE LINGUAL AND
FACIAL ARTERIES.

FROM AN EXPERIENCE OF THIRTY-NINE CASES.

By CHARLES P. CHILDE, B.A., F.R.C.S.,

SENIOR SURGEON, ROYAL PORTSMOUTH HOSPITAL; SENIOR SURGEON,
MEDICAL AND SURGICAL HOME FOR WOMEN, SOUTHBSEA.

Few surgical diseases offer a wider choice of operative procedure for their cure or relief than carcinoma within the oral cavity. There are those surgeons, for instance, who strongly advocate a preliminary laryngotomy or even tracheotomy, others who have never found any necessity for their performance; those who favour preliminary ligature of the linguals, others who never practise it and speak disparagingly of it; those who recommend the operation on the tongue and neck at one sitting, others who usually do it in two; those who remove first the tongue and later the glands, others who remove first the glands and later the tongue; those who perform Kocher's operation, which entails a communication between a septic wound in the mouth and an extensive recent wound in the neck, others who see grave objections to it on these grounds; those who frequently divide the lower jaw, others who consider it seldom necessary; and so on. The purport of the present communication is to consider the modern surgical treatment of intraoral cancer, in conjunction and in comparison with my own experience in dealing with it, with the view, if possible, of indicating what appear to me to be the most rational and practical methods to adopt. I assume that the following general statements and principles will be subscribed to by all modern surgeons.

1. *The Necessity of a Wide Local Removal.*—This will usually mean the sacrifice of not less than half the tongue, frequently of the whole tongue, sometimes of a considerable portion of the floor of the mouth, part of the lower jaw, even exceptionally of the upper jaw, side wall of the pharynx, etc., according to the position and extent of the growth. Wherever the disease is situated, to be considered at all hopelessly operable, it must be capable of a wide local removal, and I mean by this an excision which ensues a wide margin of apparently healthy tissue attached all round the growth. This is an important point, because cancer, distressing enough in any situation, is so peculiarly distressing in the mouth that, even as a palliative measure, to secure a non-recurrence *in situ* must be a particular aim of the surgeon. In carrying out this principle we are hampered considerably by the limitation of the cavity of the mouth: there is not the same scope for cutting wide of the tumour as in the breast for instance. If the disease, therefore, is so advanced, or so situated, or so fixed as to be incapable of a wide local removal, then in my opinion it is inoperable, because though a patient, after the dangers have been explained to him, is quite justified in risking his life in an attempt to be rid of such a terrible disease as cancer in the mouth; and though the surgeon, who knows the full extent of the misery which is in store for him, is quite justified in urging him to undergo this

risk, yet if the disease is to return *in situ* within a few weeks or months and his misery is to begin all over again, it is better to let him die once than twice, and not subject him to the trial of a serious operation into the bargain. Of course, the surgeon cannot guarantee against local recurrence, for apparently healthy tissue may contain cancer cells, but he should have this prospect particularly in view in recommending or discountenancing operation, and in whatever operative procedures he adopts. If, on the other hand, recurrence takes place in the neck, even within a short time, the case is different. The disease here, distressing enough, is so much less so than in the mouth that the intraoral operation will have been worth the doing, though if it has taken place in an early stage the patient, who will be ignorant of the misery he has escaped, will not fully appreciate the surgeon's effort.

2. *The necessity of a wide glandular dissection in all cases* in accordance with the modern principle of treating cancer surgically. This entails the removal of the fascia, fat and lymphatics from the submaxillary triangle (including in all cases the submaxillary salivary gland), and from the anterior triangle, down to the sheath of the great vessels, as well as the deep chain of lymphatic glands beneath the sterno-mastoid, from the clavicle to the atlas. The necessity of performing this extensive operation on both sides in all cases has not been finally determined. If the disease crosses or even approaches the mid-line in the tongue or floor of the mouth it is demanded: it is also demanded if the disease, though unilateral, is situated towards the base of the tongue, because there is a free communication across the mid-line between the lymphatics of that part. If the disease is situated anteriorly and is strictly unilateral the general opinion is that a dissection of one side is enough. Sufficient evidence to settle this question is not at present forthcoming, and surgeons and pathologists should direct their attention to it. Da Costa has recently recorded a case in which, the primary disease being strictly unilateral, the glands on both sides of the neck were secondarily affected. The matter is an important one for decision, because a bilateral neck dissection adds considerably to the severity of the operation.

3. Consequent on (1) and (2), the operation is very severe and serious. But there are other well-recognized circumstances which make it especially dangerous. Patients with cancer in the mouth are usually getting on in life: they are frequently quite old; they are often the subjects of past syphilis, over-indulgence in tobacco and alcohol, as well as of the bronchial troubles that attend advancing years. They are not, therefore, the best subjects for major operation. In addition, there are special dangers attending the operative procedure itself. There is during the operation the danger of hæmorrhage and of asphyxia owing to the entry of blood into the air passages. Subsequently, there is the danger of shock, of inhalation pneumonia, and of septic cellulitis owing to communication in some of the operations—Kocher's, for instance—of a septic wound in the mouth with a large recent wound in the neck. Lastly, excision of the tongue is an operation in which the psychic element is an unfavourable factor. The idea of losing his tongue, even in a successful operation, is depressing to the patient, and probably influences the result in some cases. The causes of a high primary mortality, therefore, are not far to seek, and the importance of avoiding those that are avoidable must be kept in view in determining the choice and scope of operation.

4. *The desirability of performing this operation as of all operations at one sitting if possible.* A patient will sometimes be able to screw his courage up to face a single operation who cannot be brought to face a second. This object nevertheless, however desirable, is frequently unattainable in cases of mouth cancer.

5. *The desirability of avoiding a communication between a wound in the mouth which is necessarily septic and a large wound in the neck which otherwise there is no difficulty in keeping aseptic.*

6. *The desirability of not introducing any unnecessary procedures into an operation which of itself is quite complicated enough.* Assuming that these statements and principles are correct, the practical question is how best to conform to them in the operative treatment of intraoral cancer.

LIGATURE OF ARTERIES.

I shall first state my proposition, and subsequently give the reasons for its advocacy. The proposition is:

That in every case of intraoral cancer the neck should be attacked first, one or both linguals and facials tied, and the primary growth in the mouth should be removed subsequently, either at the same or a future sitting.

As one of the chief objects of this paper is to advocate ligature of the lingual and facial arteries, which, in my opinion, is the key to the operation for intraoral cancer, I shall consider this question first. It is strange that with such powerful supporters behind it as the late Professor Billroth and Sir Frederick Treves ligature of the lingual artery should have found so little favour generally among surgeons. I think the reason is that it was advocated under quite different circumstances from those existing at the present day. Extensive gland dissections were not then in vogue. Either gland dissections were not done at all or were limited to the perfunctory removal of an enlarged gland or two beneath the jaw or in the anterior triangle. Hence ligature of the lingual introduced an additional preliminary operation; it involved a complication, was not necessary in the hands of a surgeon of skill and experience who felt confident he could deal with the hæmorrhage without it, and perhaps was not always easy. But other surgical procedures may come up again for consideration under altered circumstances, and this question of ligature of the lingual artery is, I think, one. In the procedure advocated here—namely, attacking the neck in all cases first, ligature of the lingual assumes a different aspect. It is done as part of the dissection of the neck. Sometimes in dissecting the anterior triangle the lingual comes into view at its origin and may be ligated there. I have on a few occasions so performed it. The ligature is, however, almost always placed upon it immediately after the dissection of the neck, beneath the hyoglossus muscle. The submaxillary triangle has been dissected, the bellies of the digastrics are in full view, and the hyoglossus with the hypoglossal nerve and usually the ramine vein lying upon it. Ligature of the lingual becomes the simplest of proceedings; the anterior belly of the digastric is hooked downwards and forwards, the posterior downwards and backwards. The great cornu of the hyoid bone is felt, and just above it the fibres of the hyoglossus are divided by a few light touches of the scalpel. No director is used. With the aid of a pair of dissecting forceps and a blunt dissector or blunt end of the ligature forceps the lingual artery is invariably picked up just beneath the hyoglossus. I have never failed to find it with the greatest ease, and the operation for its ligature occupies less than two minutes. The only precaution necessary is to work gently and avoid wounding the ramine or any other veins in the neighbourhood. The ramine vein is usually seen running with the hypoglossal nerve upon the hyoglossus muscle, and is kept out of the way together with the nerve with a squirt look. The facial artery is always ligated and divided during the dissection of the neck when the submaxillary gland is lifted from its bed. It comes into view during this proceeding, and requires no looking for.

In April, 1904, almost a year before the publication of Mr. Butler's paper, I commenced extensive glandular dissections of the neck in malignant disease within the month. On April 4th, 1904, I performed the following operation at the Royal Portsmouth Hospital:

The patient had an epithelioma involving the whole of the right side of the tongue and dorsum to opposite the faucial pillar, and extending into the substance of the tongue on the left side. Enlarged glands were felt in the right submaxillary and anterior triangles—none in the left. The following account of the operation is taken from my notes: The left submaxillary region was dissected out, including the submaxillary salivary gland, and the left lingual and facial arteries were tied. An incision was then carried from the mastoid process on the right side along the sterno-mastoid muscle to 2 in. above the clavicle, and one to join it was carried up to the symphysis menti opposite the hyoid bone. Skin flaps, including playisma, were reflected. The glands, fascia, and fat were cleared out of the anterior and submaxillary triangles (including the submaxillary salivary gland), as well as the deep chain beneath the sterno-mastoid muscle. The right lingual and facial were tied. The tongue was then split and the right half was brought out through an incision in the mucous membrane of the mouth beneath the jaw and removed (Kocher's method). The left half was excised intraorally, as an attempt to pull it out through the wound stopped breathing. The operation was performed at one sitting,

and the patient made an excellent recovery. He subsequently died of recurrence in the neck.

At the operation the glands were found infiltrating and breaking down, and the prognosis was consequently very unfavourable. When I began these extensive glandular dissections of the neck for intraoral cancer, I began to practise at the same time ligature of the lingual and facial arteries in all cases, and I shall state now the advantages that have appeared to me to attend this practice. My experience extends to ligature of these arteries on 39 occasions.

1. *It reduces the excision of the tongue to a practically bloodless operation.* Mr. Jacobson, in his remarks on ligature of the lingual artery in excision of the tongue, makes the following criticisms:

(a) "In 3 cases in which I know of this precaution having been taken, the hæmorrhage was as free as in the usual operation with scissors, performed without any such preliminary," and in a footnote he gives as the reason that the lingual was probably tied in front of a large dorsalis lingue.

The only answer one can give to this is that Mr. Jacobson's experience must have been singularly unlucky, and likely enough to prejudice him against the procedure. In the 39 cases of ligature of the lingual in my own experience, this has never occurred. I always pull the lingual well up and place the proximal ligature as far back as possible to avoid this contingency, though I have never seen the dorsalis lingue, and I always divide the artery between two ligatures to make quite certain that I have ligated it. In all of my cases it has reduced the excision of the primary growth to a bloodless operation, very much as it would be in the deadhouse. With few exceptions, these patients have been operated upon at the Portsmouth Hospital, where I have over and over again demonstrated to those who have done me the honour of being present the simplicity to which it reduces the subsequent excision of the growth in the mouth. Hardly ever any artery spurts at all. The facial has already been tied in removing the submaxillary gland. By these manœuvres not only has the blood supply of the tongue but of the gums and floor of the mouth been cut off, this being furnished almost entirely by the sublingual branch of the lingual and the submental branch of the facial. With regard to venous bleeding, this, as a rule, is quite trivial, as might be expected. The tongue and floor of the mouth are terminal circulatory organs. No large venous trunks are present in them, and the venous bleeding is consequently slight. The only cases in which I have found it at all troublesome are when the disease is in the tonsil and its neighbourhood, from the pharyngeal plexus and inferior palatine veins. Mr. Jacobson's second objection to ligature of the linguals is

(b) "I think that an experience derived from operations in over 50 cases justifies me in saying that if the operation with scissors be performed with attention to the details given above, the hæmorrhage is not so difficult to deal with as to require this precaution." And in a footnote he adds: "In writing this I am taking it for granted that the surgeon will be aided by help as apt and ready as I have been fortunate enough to find."

This in some cases may be taking a good deal for granted, but with this "if" the statement is no doubt correct. It is admitted that to those experienced in excision of the tongue, and who have skilled assistance at their disposal, the control of hæmorrhage is not a very difficult matter. But I think it will be equally admitted that the less blood these patients, often old and broken down with suffering, lose the better. In the hands of surgeons even of experience I have more than once seen a patient lose a considerable quantity, and even a large quantity, of blood before the completion of the operation, and I have been told by ex-house-surgeons of other hospitals that in the usual operation, without ligature of the linguals, post-operative hæmorrhage is not a very uncommon event for them to have to deal with. Mr. Jacobson says: "That the hæmorrhage is free with the scissors alone, none will deny." Why have hæmorrhage at all? For the safe, easy, and rapid removal of the uterus we tie, as a preliminary measure, the ovarian and uterine arteries; for the safe, easy, and rapid removal of the thyroid we tie the thyroid arteries; for the safe, easy, and rapid removal of the tongue we should tie the lingual. Whether the patient lose a large or small quantity of blood; whether hæmorrhage be difficult or easy to control, ligation of the lingual

and facial eliminates it, and must surely, therefore, be an advantage. As stated above, I have ligatured the lingual and facial arteries on thirty-nine occasions, on one or both sides, previous to excision of cancer in the tongue or floor of the mouth, in all possible situations, at one sitting or more. In almost every case in the latter operation no vessel whatever has required a ligature; in the remaining bleeding has been of the most trivial character. In not a single instance has there been any post-operative hæmorrhage, either reactionary or secondary. Mr. Jacobson's third line of criticism against ligature of the lingual is (c) that it is not an easy operation, and cannot always be done quickly. I do not think the difficulty of an operation alone should deter a surgeon, though the time occupied in performing it, perhaps a natural sequence of the difficulty, would undoubtedly in these cases be an argument against it. But this criticism applies to ligature of the lingual artery independently of the dissection in the neck, and therefore is not relevant to the operation I am discussing here. As I have stated above, ligature of the lingual after dissection of the neck is a simple and easy procedure, and adds practically nothing to the duration of the operation.

2. Owing to the elimination of the one and only troublesome complication of the operation within the mouth—namely, hæmorrhage—it greatly enhances its rapidity and simplicity. It reduces the actual excision of the tongue to a minor operation, which it never is without it. It consequently frequently enables the surgeon to perform an operation at one sitting which he would otherwise consider it prudent to divide into two. If, for instance, the disease is confined to the tongue and at the termination of the gland dissection the patient is in good condition, and the surgeon's judgement prompts him to remove the tongue or half the tongue at the same sitting, he knows that he has quite a trivial and bloodless operation in front of him: whereas if the tongue is excised first, and the operation has been troublesome and the patient has lost a good deal of blood, the surgeon will hesitate to submit him to a long dissection of the neck immediately afterwards. After ligature of the feeding arteries the mouth operation (unless the jaw has to be divided) becomes quite insignificant; the gland dissection is the only major operation.

3. Owing to the elimination of hæmorrhage, it enables the surgeon to excise the growth in the mouth with greater precision and deliberation. This is, perhaps, its greatest advantage. The surgeon can see exactly what he is doing and where he is cutting—a matter of great importance in dealing with this disease in a confined, and not always easily accessible, cavity.

4. If, as in many cases of extensive disease, it is considered prudent to divide the operation into more than one sitting, it cuts off the blood supply to the growth meanwhile. As Sir Walter Cheyne has pointed out, the growth in the glands is frequently more rapid than in the mouth. On this ground alone it would in many cases be wise to remove the glands first. If we can put a brake on the blood supply to the primary growth at the same time it is an additional reason for attacking the glands first, for if the tongue operation is performed first we cannot in the interval cut off the blood supply to the glands.

5. Ligature of the lingual and facial arteries may starve any cancer cells in the neighbourhood which have been left behind after the completion of the operation, and in this way possibly prevent or retard recurrence. It is impossible to prove this, but it is not an unreasonable supposition, or one unsupported by experience. The ideal modern operation for cancer is to remove the entire disease—and I mean by this the primary growth and every cancer cell which has sprung from it—in one piece. This is best exemplified in the case of the breast. The ideal is to remove the breast, a wide margin round it, the lymphatics running to the axillary glands and the axillary glands themselves, all in one piece inclusive, with the object of having in the removed portion every cancer cell. That is the objective, possibly seldom attained. In the tongue this is impossible. It is impossible to remove the tongue and glands of the neck in one piece. Tissues remain between the primary focus in the mouth and the removed portions in the neck, which may and probably do contain cancer cells. Also, notwithstanding the most careful dissection, cancer cells may be left—indeed, certainly often are left—in the neck. By cutting off the blood supply to

these as far as possible, we may succeed in retarding their growth or even in starving them out altogether. This is further aided by the cicatricial contraction of the large wound in the neck and in the mouth. Mott was the first to suggest ligature of the feeding arteries to inoperable malignant tumours. The same principle may be extended as an additional aid to those that are operable. We have a hint in this direction from the natural history of such tumours. The rapid and luxuriant growth of malignant tumours containing little formed fibrous tissue, and in a soil composed of young and vascular elements, the comparatively slow growth of tumours containing abundance of well-formed fibrous tissue, and in a soil composed of less vascular and atrophied elements, would suggest that cutting off the blood supply and producing abundance of cicatricial tissue in the neighbourhood of cancer cells is likely to destroy them or retard their growth. In the mouth and neck by the cicatrization of the large wounds there, after the extensive modern operation for cancer, and by greatly diminishing the blood supply to these parts by ligature of the lingual and facial arteries, especially if it be done on both sides, we are in a position to produce conditions which we know to be unfavourable to the growth of cancer naturally.

6. It does away with any necessity for preliminary laryngotomy or tracheotomy. Now opening the air passages and plugging the fauces, however simple a proceeding, introduces an additional complication, makes a wound which, owing to its communication with the air passages, is necessarily a septic wound, and should be avoided if possible. In fact its advocacy is an admission of the anxieties of hæmorrhage and its consequences in excision of the tongue. After ligature of the lingual and facial arteries it has in my experience never been necessary. In no single instance has the entry of blood into the air passages been a source of anxiety. It is admitted that with a skilled operator, skilled assistants, and a skilled anaesthetist, this operation may not be required, even if the lingual and facial arteries are not tied, but the latter operation greatly reduces the anxiety of blood entering the air passages, and renders preliminary laryngotomy or tracheotomy quite unnecessary.

I have stated the advantages that have appeared to me to follow an attack upon the neck first, with ligature of the lingual and facial arteries, from the experience of a considerable number of cases. Another argument for attacking the neck first is this—it is a contingency that may not often occur, but it is not without the bounds of possibility: If the tongue is removed first the patient may subsequently decline the operation upon the neck. All that is troubling him at this time is the disease in his mouth. Although he may have had it clearly explained to him that a second operation will be necessary, and although he may have made up his mind to submit to this, after he has gone through the experience of the first, and has got rid of all appreciable evidence of his disease, he may be unreasonable or his courage may forsake him, and he may refuse the second; whereas if the glands are removed first he is not likely to refuse the subsequent removal of the disease in his mouth. Patients, especially hospital patients, are occasionally very unreasonable, and no amount of argument will persuade them to follow the surgeon's advice.

The last point which I wish to emphasize, in the choice and scope of operation for intraoral cancer, is the advisability of avoiding a communication between the wound in the mouth, which is necessarily septic, and the large recent wound in the neck left after a glandular dissection. This can always be done, except, I believe, the growth be in the tonsil and its neighbourhood, and requires excision from without. Provided the disease be confined to the tongue, this can always be excised intraorally; and if the disease is in the floor of the mouth, any communication with a large recent wound in the neck can always be avoided by dividing up the operation into two stages.

Typical positions of intraoral cancer may be conveniently taken, with the view of indicating the *modus operandi* in carrying out the principles advocated in this article.

1. *The growth is confined to one side of the tongue, in a median or anterior position (with or without a slight adjacent involvement of the floor of the mouth).* This is the simplest case. The surgeon proposes to clear the anterior and submaxillary triangles on one side, tie the

facial and lingual arteries, and then remove half the tongue. Butlin's skin incision is made. There is no necessity to describe minutely the dissection. Commencing from below, and carrying the dissection upwards as far as the parotid gland, and forward to beyond the mid-line, the whole contents of the triangles down to the great vessels (including the submaxillary salivary gland) are removed in one piece. When the submaxillary gland is lifted from its bed the facial artery comes into view, is ligated and divided. The internal jugular vein may require removal. The carotid vessels are next pulled forward, the sterno-mastoid muscle backward, and the deep chain of glands posterior to the vessels are next dissected out in one piece from the clavicle to the transverse process of the atlas. As the final step in the operation on the neck the hyoglossus is divided and the lingual artery tied and cut between the ligatures.

The wound is now closed, a rubber tube being brought out at the lower end, and no gauze packing being used. Gauze packing, which I used in my earlier cases, frequently sticks to the edges of the skin and acts as a retainer of discharges instead of a drain. The best plan, in my opinion, is to insert one rubber tube at the lower end of the incision and place a sponge or two in the dressing to ensure elastic compression of the large wound and thus prevent oozing. The wound in the neck, having been closed, is covered temporarily with a towel soaked in 1 in 40 carbolic acid to protect it from contamination during the excision of the tongue. This can now be usually performed straight away, being quite a minor and bloodless operation, and occupying only a very few minutes. After the excision of the tongue the gloves are changed, and the dressing is applied to the wound in the neck. If for any reason it be considered prudent to defer the excision of the tongue—though if the operation is performed in this order and in this way it will not often be necessary—it can be done in a fortnight, the blood supply to the primary growth having been cut off in the interval. At this second operation there will likewise be no bleeding, notwithstanding any theoretical considerations about the establishment of collateral circulation.

2. *The growth is confined to the tongue, but crosses or approaches the mid-line (with or without a slight adjacent involvement of the floor of the mouth).* Both anterior and submaxillary triangles will require dissection, and the whole tongue must be excised intraorally. This is a very severe operation, and the surgeon can proceed in two, or exceptionally even three, stages, according to the circumstances and condition of the patient. I have more than once successfully dissected out both anterior and submaxillary triangles, tied both linguals and facials, and subsequently excised the whole tongue intraorally at one sitting. Still, further experience convinces me that the operation is too severe, and as a rule two sittings will be required. I think they are best arranged as follows: At the first operation the triangles upon one side are dissected with ligature of the lingual and facial. A fortnight later a similar operation is performed on the other side and the tongue then excised. Alternatively the neck dissection might be done on both sides at the first sitting, with ligature of both linguals and facials. In one case, however, in which this operation was performed, sloughing of the anterior portion of the tongue followed, though this *contretemps* did not interfere with the patient's recovery. This is the only single accident that has happened in my series of cases of ligature of the lingual. The first plan, therefore, seems the best. If the patient's age or condition involves great anxiety as to how much he will be able to stand, the operation can even be performed in three sittings, a neck dissection on each side separately and a subsequent excision of the tongue.

3. *The floor of the mouth is extensively involved either laterally or in front.* The operation here, I think, requires a median division of the jaw, and should always be done in two stages, exceptionally in three. The first operation, as a rule, will consist in a dissection of both anterior and submaxillary triangles, with ligature of both lingual and facial arteries. In a fortnight, when the wound in the neck is healed (the blood supply to the growth having been cut off in the interval), the lower jaw is divided in the mid-line, and the disease, wherever situated, is widely and bloodlessly excised. The jaw should always be wired, because, though it frequently does not unite by bone, yet

the wiring ensures a good position for it subsequently, and in my experience its non-union causes very little inconvenience. A portion of the lower jaw may require removal. Finally a drain tube is carried from the mouth to the lower angle of the wound in the neck and kept in position for about a week. The large wound in the neck caused by the dissection of the triangles a fortnight earlier having healed, there is now no danger of cellulitis in the neck. Three sittings may occasionally be required for excision of the disease in this situation, as exemplified in my last case at the Portsmouth Hospital.

The patient was a feeble old man, said to be 65—he looked 75. The disease occupied the left side of the floor of the mouth and both halves of the tongue. On June 22nd, 1908, the left neck dissection was performed with ligature of the lingual and facial on that side. The patient's condition did not allow of more; the wound healed by first intention. On July 6th the right side was similarly treated, and with the same result. The blood supply to the growth had been cut off. He was not fit for the final operation till July 31st. The lower jaw was divided and the whole tongue and floor of the mouth were excised. No vessel required a ligature. One or two small vessels alone spurted in reflecting the lower lip (inferior dental). He made an uninterrupted recovery.

I am confident the operation could only have been safely done in this piecemeal and bloodless manner.

4. *The disease occupies the tonsil and its neighbourhood—for example, fauces, palate, pharynx, etc.* The consideration of these cases will be very brief, as the present article is not intended to cover them. They will usually have to be dealt with by one or other of the operations of pharyngotomy, and the operation will, I think, have to be performed in one stage, for if the neck dissection is done first anatomical landmarks will be obliterated during the cicatrization of the neck wound, which will make the excision of the primary tumour from without exceedingly difficult and dangerous. I have operated upon three such cases during the past two or three years.

In two of them, in which the disease involved the tonsil and its immediate neighbourhood, the glands of the neck were dissected out and the lingual and facial arteries were ligated close to their origins from the carotid. An incision was then carried up to the angle of the mouth, and the lower jaw was divided opposite the masseter. This gave very good access to the disease, and there was during its removal practically no arterial bleeding and no necessity for laryngotomy or tracheotomy.

In the third case the disease involved the tonsil, soft palate, and the alveolus of both upper and lower jaws, being very extensive within the mouth. As is not very infrequently seen in cases of extensive primary growth, the disease seemed to be extending itself locally, and there was very little glandular enlargement. An attempt was therefore made, at the patient's earnest insistence, to eradicate it. The neck dissection was first performed and the external carotid tied. To lessen the danger of secondary hæmorrhage the lingual, facial, and superior thyroid were next ligatured. The growth was exposed in the same way as in the two preceding cases. After median division, the lower jaw on the side of the growth, being involved, was disarticulated, and a large section was also removed of the neighbouring alveolus of the upper jaw, to which the disease had extended. There was no arterial hæmorrhage, though the bleeding from the inferior palatine and pharyngeal veins caused a little trouble. This patient made an excellent recovery, and followed his employment as a cabdriver for a year, when he had recurrence *in situ*. There was never any sign of disease in the neck.

In all these cases the disease was removed with scissors, and in all of them the advantage of preliminary ligature of the feeding arteries was manifest. In none of them was laryngotomy or tracheotomy required. In none of them was it possible to close the wound in the pharynx. The same principles as advocated in this article for dealing with cancer of the tongue and floor of the mouth were extended to these cases, except that the operation was in each instance performed at one sitting, involving a communication between the mouth and the large wound in the neck, and thereby greatly increasing its risks. But if a clean dissection of the contents of the triangles is carried out I do not see how this is to be avoided.

CONCLUSIONS.

To sum up, the following are the two main principles advocated in the present communication in the operative treatment of cancer of the tongue and floor of the mouth:

The neck should always be attacked first, with ligature of the lingual and facial arteries on one or both sides. This manœuvre reduces the excision of the primary growth, provided that it can be extirpated without division

of the jaw, to an insignificant and bloodless operation, which can consequently be frequently performed without danger immediately after the neck operation. It enables the primary growth to be removed with greater precision. It does away with all necessity for preliminary laryngotomy or tracheotomy. It cuts off the blood supply to the tumour in the interval, if the operation has to be divided into two stages. It will possibly starve cancer cells which may be left behind after attempted extirpation of the disease. In my experience it is the key to the operation.

The second principle is that a communication between the mouth and a large wound in the neck should always be effected where possible. Unless the disease be situated in the tonsil or its neighbourhood, and except the patient insist on a single operation, this can always be accomplished by dividing the operation into two stages in those cases in which for the satisfactory removal of the disease the lower jaw requires division. The neck, as before, is attacked first, and the lingual and facial arteries are tied. When, in a fortnight, the large wound in the neck is healed, the jaw is divided and the primary growth is excised, as before, bloodlessly. In conclusion, as regards final results, early diagnosis is the only hope. With this view, the therapeutic test of cancer, iodide of potassium, should be relegated to the limbo of dangerous playthings. Immediate microscopic examination of a piece of the growth should be the only test, and the therapeutic test should never be employed unless the microscopic report is doubtful. It should then be pushed rapidly, and its effects not watched too long.

THE SURGERY OF COLITIS.

By F. C. WALLIS, F.R.C.S.

SURGEON TO CHARING CROSS, ST. MARK'S, AND GROSVEGOR HOSPITALS.

BEFORE discussing the present position of the surgery of colitis, it is necessary to have a clear idea as to what the word "colitis" is meant to convey. For the purposes of these remarks, it is intended to include acute and chronic affections of the colon, sigmoid, and rectum produced by catarrh, inflammation, infection, or intestinal irritation.

It is not too much to say that now practically every morbid condition of the large bowel and rectum has been relieved by surgery at one time or another, and although there is not yet, and cannot well be, any decided line drawn as to which cases should receive one or the other treatment, it becomes a daily increasing necessity for the surgeon to be familiar with the causation and pathology of these conditions as well as to have an intimate knowledge of their treatment.

Colitis must be divided first into two large groups, Acute and Chronic, the subacute being merged into the chronic, far the larger group of the two.

ACUTE COLITIS.

For practical purposes it may be said that all cases of acute colitis are infective in origin, which does not mean that all infective cases of colitis are acute.

Mention must be made of those cases which are brought about by exposure to cold, etc. Such hardly come within the scope of this paper, as when uncomplicated they usually get well with ordinary medical measures. But when there is in addition a well-marked condition of oral sepsis which has probably been present for years, a very different state of affairs may supervene.

The large bowel swarms with micro-organisms which in the ordinary way do no harm, but when the membrane is inflamed the resisting power is much diminished, and the streptococci make active use of it, with the result that serious and wholesale destruction of the mucous membrane occurs, and at the same time considerable toxic absorption takes place, producing grave constitutional disturbances.

SYMPTOMS.

These are acute abdominal pain associated with tympanites, diarrhoea, haemorrhage, and the passage of much blood-stained mucus and foul discharge, and in advanced cases sloughs may come away. A marked condition of toxæmia is always present in acute cases.

Treatment.

The surgical treatment in these acute cases does not differ from that which is done in the subacute cases, and the details will be given with the description of the subacute cases. The only point to emphasize here is that the condition is one of great emergency, and as such must be considered in undertaking any operation for its relief.

CHRONIC COLITIS.

The far larger group of chronic cases may be classified as follows:

1. Mucous colitis.
2. Membranous colitis.
3. Ulcerative colitis.
4. Haemorrhagic colitis.

Mucous and membranous colitis are practically the same, as both are due to excessive secretion of mucus.

The excessive secretion is caused by inflammatory irritation of the secreting glands, and when the inflammation is recent and subacute the discharge is entirely mucous, but in the acute cases the mucus is bloodstained.

When the inflammatory area is situated in the rectum or sigmoid the discharge consists of mucus only, but if the affected area is higher up in the colon it will be mixed with the intestinal contents. When the inflammation is of a chronic character, the mucus is secreted more slowly and becomes laminated, forming in some cases a complete cast of the bowel. This is the condition which is known as membranous colitis.

Ulcerative Colitis.

Ulcerative colitis (chronic) is a further stage of the inflammatory process, in which a destruction of tissue has taken place. Four varieties may be considered here, namely:

1. Follicular ulceration.
2. Ulceration due to sepsis.
3. Ulceration due to traumatism.
4. Dysenteric.

Follicular ulceration occurs mainly in the sigmoid and upper part of the rectum, as it is in this part of the intestinal canal that the majority of the solitary follicles exist. They are situated in the mucous membrane itself and the base of the follicle extends to the submucous tissue. The sigmoidoscopic examination shows a number of sharply-cut-out ulcers extending down to the submucous coat, and the mucous membrane around the ulcer is inflamed.

The symptoms mainly consist of a discharge of blood or blood-stained mucus; there is little or no pain associated with it, and the patients are otherwise quite healthy.

This form of ulcerative colitis is not of any serious importance as to the suffering it entails, but it is probably quite as difficult to cure as any of the different forms of colitis.

Ulceration due to sepsis when originally in the colon is due to a microbic infection of an already inflamed mucous membrane, and in ulcerative colitis associated with haemorrhage the organism present is usually a streptococcus. The contents of the large bowel, as has already been said, swarm with micro-organisms which in the ordinary way do not affect the mucous membrane; but when this is inflamed the micro-organisms not only have a destructive action on the inflamed membrane, but, in addition, the absorption of toxins causes constitutional symptoms of more or less gravity.

Traumatic ulcerations apart from ulceration due to post-operative sepsis are almost restricted to women in whom the pressure of the fetal head in a protracted labour has caused absolute destruction of a part of the mucous membrane, which sloughs away, leaving an ulcerated area behind it.

Dysenteric ulceration, as far as symptoms and surgical treatment go, does not differ from the other forms mentioned, except for the fact that the patients have usually resided in tropical countries where dysentery is endemic, and that whilst in these parts they have suffered from symptoms associated with dysentery.

It is rather necessary to put it in this way, because it is only too commonly the custom in tropical countries to class all forms of subacute and chronic diarrhoea as dysenteric, and in military hospitals when the ulceration is discovered as well, it is nearly always diagnosed and treated as syphilitic. With regard to this latter form of ulceration as a cause of colitis, I purposely have not

considered it, as after nearly twenty years of general hospital work and twelve at a special hospital, in addition to general surgery, I am quite ignorant of the existence of this form of ulceration, as I have never seen any single case of it.

Haemorrhagic Colitis.

Haemorrhagic colitis is no doubt another form of the ulcerative type, and the organism responsible is nearly always a streptococcus, but the main symptom—namely, haemorrhage—is so prominent and so urgent that the condition must be treated as an acute one with regard to the immediate treatment required.

In addition to the haemorrhage there is usually a raised temperature, the pulse is running and weak, the patient is markedly anaemic, the abdomen is tender and tympanitic, and the frequent action of the bowels, consisting mostly of blood, are accompanied with much pain and distress to the patient.

When the bowel is examined with the sigmoidoscope the mucous membrane of the rectum and of part of the sigmoid is seen to be intensely injected, and when this condition occurs in a young adult it may be easily mistaken for a malignant growth until examined with the sigmoidoscope.

There is one other condition which may give rise to similar symptoms—namely, when an inflamed appendix situated in the pelvis involves the rectum in its inflammatory process. Here, again, short of opening the abdomen it is almost impossible to make a diagnosis without the sigmoidoscope.

Treatment.

The whole aim of the surgical treatment is to clear out the large bowel as thoroughly, and render the contents as aseptic, as possible. When this has been done for some days, and at the same time oral sepsis has been thoroughly carried out, the inflammatory condition of the colon gradually subsides, and in recent cases the mucous membrane becomes normal, the symptoms disappear, and the patient is cured, but it is most necessary that for some time after every care should be taken in the way of diet, and also over-exertion should be carefully avoided; otherwise the symptoms are sure, in some measure, to return.

The point of paramount importance is to settle as exactly as can be, first, when surgery should come in, and, secondly, what particular thing should be done for each particular case. At present only those cases come to the surgeon which, so to speak, are driven to a surgical port by stress of circumstances. These, as a matter of fact and speaking from experience, do very well in the end, although the period of convalescence may be a matter of months, which, however, is passed without pain and, indeed, in comparative comfort.

The question as to the amount of time which should be spent in medical and expectant treatment in chronic cases is not easy to answer, but it will depend upon the amount of pain which is being endured, the individuality of the patient, and the conservative bias of the medical man.

The disadvantage of this is that no one medical man has, except in quite rare instances, a sufficient number of cases the treatment of which would constitute an experience of any real value. The decision, therefore, of the vast majority of men will be one arrived at through the medium of some one more or less expert. It is a comfort to reflect that the majority of such in this metropolis, at all events, are absolutely broad-minded as to the matter of what is called "surgical interference."

As to when this shall take place in this or that case it must be a matter of evolution, and in accordance to the results which can be shown by those of us who have the surgical treatment of these cases, and so gradually with the spread of knowledge and increase of experience one foresees a vast improvement in the future treatment of these cases of colitis, when the years which are now spent in hopeless treatment will be a thing of the past.

Dealing with acute cases, it must be apparent that such a grave condition requires urgent treatment in some thorough and practical form. Half-measures are useless; and, although those about to be advocated may in bad cases be hazardous, it is the only chance and must be

taken. The aim of the treatment must be, first, to thoroughly irrigate the large bowel, that the infective material it contains may be reduced to a minimum. It is quite impossible to do this by the ordinary methods of rectal irrigation. It is much too painful, and the patient is much too ill to stand it.

An appendicostomy, when possible, should be undertaken; or if for any reason, such as adhesions, etc., this is not feasible, then caecostomy must be performed, preferably according to the method of Gibson if circumstances permit.

OPERATIVE TREATMENT.

The various kinds of surgical treatment at present carried out are as follows:

1. Appendicostomy.
2. Caecostomy.
3. Colostomy.
4. Proctotomy (median posterior).

To these must be added, either separately or in conjunction with the above, the more recent treatment by means of

5. Cataphoresis.

Appendicostomy.

Appendicostomy is probably, taking it all round, the best operation for those chronic cases of membranous or ulcerative colitis which are at present submitted to the surgeon for operation.

The operation itself presents no difficulties unless there has been much inflammation in the caecal region, when the adhesions may be troublesome. The operation has been frequently described of late, but one or two descriptions which have been published have been so obviously written on insufficient experience that it may be as well to briefly describe the essential details.

The appendix is reached through as small an incision as is compatible with the amount of abdominal fat present, and the appendix is freed of all adhesions and brought outside the abdominal cavity, as much of the meso-appendix being divided as is necessary for the absolute free handling of the appendix; in fact, it is best to free the appendix down to the caecum.

When this has been done and all haemorrhage stopped, the incision of the peritoneum is closed, and in this process the base of the appendix is included.

These patients are mostly thin and there is not much depth of abdominal wall to close. The split muscles are united either side of the pulled out appendix, but the skin is for the moment left. The appendix is packed round with gauze, and a point chosen to amputate which would leave not more than a quarter of an inch of the appendix outside the skin; the appendix is crushed at this point in the ordinary way to avoid any haemorrhage, and after removal the cut edge is either treated with pure carbolic or with the actual cautery.

The great point of practical importance is to leave as little of the appendix as possible.

The cut edge of the appendix is seized with fine forceps and held apart whilst a catheter—rubber—of sufficient size to be tightly gripped by the stump of the appendix is passed into the caecum, a thread ligature is tied round this, and the skin is closed with interrupted stitches, which again include the appendix.

The catheter is now connected with an irrigation apparatus and a solution of warm bicarbonate of soda (100° F.) is allowed to slowly run into the colon. There is no possibility of any leakage occurring if the simple points mentioned already are carried out. To get the solution to pass out freely, and to avoid any over-distension of an attenuated colon, a small Kelly's tube is passed into the rectum; this is a most useful point in the washing out. After from 1 to 3 pints have been passed into the colon the fluid will commence to flow readily through the rectal tube, and the irrigation is carried on on the operation table until the fluid passes out quite clear and odorless. The catheter is then tied up to prevent any back leakage, the wound is dressed, and the patient put to bed.

After-treatment.

If the patient is not too ill from the anaesthetic, the irrigation should be carried on next day, and in any case

no time should be wasted in continuing the irrigation which should be carried out daily. This can be done without any disturbance of dressings. The wound is looked at on the third or fourth day, when it may be found that the exposed part of the appendix can be removed. The skin suture on either side is divided, and the appendix stump is cleaned with a solution of peroxide.

The irrigation is continued for from three to six weeks, and after the first few days it has been my custom to finish up with some permanganate of potash solution—very weak—which I have found most beneficial. Due care must be paid to the diet, and some intestinal antiseptic should be given.

If the patient is constipated—and they mostly are—some aperient in addition to the irrigation must be given. By this simple method cases of colitis which have been going on for years and have been during that period treated with all varieties of expectant treatment, show in a very short time marked improvement; hæmorrhage and pain soon cease, the patients put on flesh, and the pyrexia disappears. At the end of three to six weeks the irrigation is discontinued, but a careful diet is maintained and rest in the horizontal position is insisted on as much as possible. But very gradually the patient is allowed to resume ordinary diet and increased exercise is allowed. A careful watch must be kept over the patients, especially with regard to what is passed from the bowel. During this time and until the colon is normal when viewed with the sigmoidoscope the appendix must be kept open by keeping a plug in during the night. It can be left out during the day, and some simple dressing applied. There is practically no leakage. It may be that it is desirable to prevent the opening from closing for even a year, and if there are any indications of a "set-back" the irrigation must be resumed until these have disappeared. The best results of this treatment are seen in those bad cases of hæmorrhagic colitis where the patients are in a most desperate condition from a combination of hæmorrhage and toxæmia together. In a few days the hæmorrhage ceases, the temperature falls, and the patients lose their blanched colour and gain in weight, and in a short time the action of the bowels is normal.

But in this as in other forms of colitis it is necessary for some time to keep a careful watch over the patient both as to diet, exercise, and exposure to cold.

When it is thought safe to let the opening close, it is usually only necessary to leave out the tube, and if this is not sufficient the edges may be touched with the actual cautery, but it is rarely necessary to do this and most rarely necessary to do any form of plastic operation.

Cæcostomy.

This may be termed a bad substitute for appendicostomy, and should never be resorted to if in any way the appendix can be made use of. The details of this operation as performed by Gibson will be found in Tittle's book; the aim of the operation being to avoid any leakage from the cæcum, a result which is highly disastrous to the neighbouring skin as well as most painful to the patient.

Colostomy.

There are many ways described in which this operation may be performed, and the one advocated in my book, *Surgery of the Rectum*, is, I think, on the whole the best. The points about it are that the operation can be done through a small incision, and the great gain is that the bowel can be opened *at once*, and, as in the appendicostomy, irrigation can be proceeded with *at once*.

This operation is of the greatest benefit in cases of dysenteric ulceration, where usually the ulceration is limited to the sigmoid and rectum. The affected bowel can be kept quite clean and free from all contact with the intestinal contents, and the ulcerated areas can be treated by the direct application of any lotion which it may be thought will do good. Personally I have not much faith in the curative powers of any of these applications beyond their effect in keeping the colon clean, and as far as possible preventing reinfection. This is probably all that is necessary in those cases in which the ulceration is limited to the surface, and there is no submucous infiltration. When once the ulcerated surface has healed it is well to close the colostomy forthwith that the rectum may resume its natural functions. This will

materially help in the prevention of any contraction, any tendency to which must be overcome by the careful passage of bougies.

Posterior Median Proctotomy.

This is of great use in those cases in which the ulceration is low down in the rectum, and the pain is so great that there is much spasm of the sphincters. A posterior incision through both sphincters and extending back to the coccyx relieves the spasm and ensures free drainage, and after a day or two the rectum and sigmoid can be thoroughly irrigated with very little discomfort to the patient. This, associated with warm boric acid sitz baths, soon relieves the patient of the painful and acute symptoms, and the ulcerated surface can after a week or ten days be submitted to the treatment of zinc cataphoresis.

This combination of treatment is of the greatest value in those cases in which the ulceration is limited to the lower part of the sigmoid and the rectum.

Cataphoresis.

This form of treatment was advocated by Dr. Ironside Bruce and myself in a paper read at the Royal Medical Society in June, 1908. For the details of this treatment I would refer my readers to that paper. I have nothing but good to report of the further experience of it, and certainly in recent cases the effect is most satisfactory. The effect of a continuance of the treatment in those intractable forms of ulcerative proctitis of some years' standing with submucous infiltration is that the spreading of the ulceration is checked, and in those cases where after years of ulceration the membrane has been damaged beyond repair, a non-infective granular surface is left which can be dealt with by means of excision or some other surgical measure, which when embarked on in the ordinary way is in many cases futile, or even worse, on account of the infective character of the ulceration, and the consequent difficulty of preventing reinfection.

CONCLUSIONS.

To sum up the present position of surgery in the treatment of colitis, it may be said that the sooner all forms of ulcerative and hæmorrhagic colitis are submitted to surgical treatment the better. There can be no doubt but that irrigation of the bowel through a surgical hole made in it is the best—one would almost say the only—chance there is of recovery from this condition. Mention has already been made as to the serious condition which exists in acute cases, and the one chance they have, however great the risk, is the free irrigation of the large bowel by one of the surgical measures already suggested.

In either acute or chronic cases the whole aim and object of both medical and surgical treatment is to get the colon free of the infective contents, and thus, by keeping the bowel clean, give it the best chance of recovery.

Any application of a chemical nature, whether stimulant or astringent, must be used with caution, as most such applications are irritant, whatever other properties they possess.

The best treatment for these ulcerated areas is cataphoresis, but so far we are only able satisfactorily to treat those cases limited to the lower 7 or 8 in. of the bowel.

As to the efficacy of vaccines in either acute or chronic cases, my experience is quite small and limited to chronic cases, in which it seems to have some beneficial effect, although so far it in no way seems curative. From inquiries made, I gather that the present state of our knowledge in this matter is insufficient to make any definite statement either one way or the other.

The form of colitis about which any definite conclusion as to surgical procedure cannot yet be arrived at is membranous colitis. This form is usually met with in women between the ages of 25 and 50; they are nearly always of the neurotic type, imaginative and constipated from habit, and generally before they come for treatment for colitis they have either been treated or have treated themselves for years for constipation, usually by wrong methods, which have had the effect of exaggerating the inflammatory condition of the mucous membrane and increasing the mucous discharge.

Muco-membranous colitis of this type has often been said to be caused by the neurasthenic condition. As to

how far this statement is one of fact is a question which it is not proposed to examine further than to suggest that it may be possible that, owing to the constant absorption of toxic products, the various neurasthenic features may be due to the direct effect of these absorbed toxins on the central cerebro-spinal system, and if this is so it would seem obvious that any measure which quickly and thoroughly cleans the colon of its harmful products must be the most desirable.

Without discussing the various treatments by means of lavage, diet, waters, exercises, and intestinal antiseptics which are carried out in this country, at Plombières, and elsewhere, with marked success in many cases, there remain a large number of cases which, either from neglect or in spite of treatment, are in a miserable condition of chronic ill-health, which no amount of treatment can do much to alleviate. It is for such cases that I would suggest a much earlier resort to surgery. It does not appear to be possible to clear the colon of its contents by the ordinary methods of lavage; besides which the process, if carried out effectively, is distinctly an exhausting affair, especially having regard to the enfeebled state of the individual concerned. When once the operation of appendicostomy has been performed the process of washing out the colon is one which is easily carried out with the smallest amount of discomfort to the patient, and with a rapid disappearance of the amount of membrane and great amelioration of the symptoms, such as pain, flatulence, etc. The constipation is not so easily overcome, but there is distinct improvement in this respect, and the appetite is greatly improved, the weight increases, and with the improved physique the recuperative powers are increased, and with a continuance of the treatment, with due regard to diet, and with as perfect hygienic surroundings as possible, there is no reason why these people should not get well; but the treatment may take many months—even a year—before the patient is able to discontinue it and allow the opening to close.

In some—nay, in most—cases the patients bear the treatment with equanimity because of the greatly increased comfort they derive from it.

There is not any necessity for these people to stay in hospitals or nursing homes longer than two or three weeks, as for the purpose of carrying out the treatment the patient can soon learn to do this with any slight help from some member of the family or a servant.

Perhaps the most important thing in diagnosis in reference to treatment is the early examination by the sigmoidoscope.

There is no doubt that much may be learned from such an examination and a great deal of time saved, and I would strongly urge that this should be done quite early. The state of the bowel wall can be made out and specimens of pus or secretion can be obtained for microscopical examination or for bacterial investigation; the extent and depth of any ulceration can be made out and the question of any growth can be settled. With the sigmoidoscope for diagnosis and the various surgical methods which have been described much can now be done to relieve the various forms of colitis. The important question is whether these surgical measures should not be resorted to much earlier and more frequently than is now the custom.

THE University of Leipzig will celebrate the 500th anniversary of its foundation in August, 1909.

THE will of the late Dame Frances Russell Reynolds directs that a sum of £1,000 shall be paid to the National Hospital for the Paralyzed and Epileptic for the maintenance of a bed in memory of her husband, the late Sir Russell Reynolds.

It is apparent from a paper read by Mr. Berry at the Scottish Institute of Brewing on "The Condition and Head on Beer," that the public demand for a beer with an attractive "head" is more exacting than it was some years ago. In consequence, many brewers now resorted to carbonating beers. In the days of the East India pale ale, when much higher alcoholic beers were in vogue, the production of an attractive and lasting "head" did not present the same difficulties as the present day. Science has now come to the aid of the brewer, and by careful and judicious malting, methods could be employed that would produce, even on low alcoholic beers, a head and conditions of surpassing attractiveness.

THE TREATMENT OF CHRONIC RHEUMATIC AND RHEUMATOID ARTHRITIS BY RADIANT HEAT AND CATAPHORESIS.

By C. F. BAILEY, M.D. LOND., M.R.C.P.

ASSISTANT PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL, AND MEDICAL OFFICER IN CHARGE OF THE ELECTRIC DEPARTMENT.

It appears reasonable in the present state of knowledge of the pathology of the conditions included under the terms "chronic rheumatic arthritis" and "rheumatoid arthritis" to accept, for purposes of treatment, the view that they are inflammatory affections of a progressive character, probably caused by toxins elaborated by micro organisms; also, that the micro-organisms or micro-organism in question may have their habitat in the joints affected, or may dwell elsewhere (perhaps in the naso-pharynx, perhaps in some portion of the alimentary tract); also, that circumstances which depress the general or local circulation, allowing the blood to more or less stagnate in the structures which form the joints (and the circulation is normally comparatively slow in these structures), act as strong predisposing causes; that, of these depressing circumstances, one of the most important is continued exposure to cold and wet, or both combined, others are insufficient nutrition and mental shock; and that another predisposing cause may be repeated slight traumas, for it always appears from the history that the joints which have been exposed to the greatest wear and tear are usually the first to succumb.

Unless we start with some such definite, although perhaps hypothetical, view of the pathology of the affections, treatment tends to be empirical. Assuming, therefore, that the above microbic theory is correct, the value of improving nutrition by generous diet, cod-liver oil, and fats is manifest; as also the prescription of drugs empirically found to produce a good effect—and all being more or less antibacterial, such as iodides, arsenic, quinine, and guaiacol—and more especially the removal of our patient from the influence of the predisposing causes.

The comparative want of success in one portion of our treatment lies in the fact that, although we may give drugs as remedies in large doses and for long periods, yet the actual amount at any time of any drug circulating slowly in the joint tissues is in reality quite small, and, therefore, the beneficial effect is proportionate. To increase the latter the treatment by radiant heat and cataphoresis may assist us materially.

The action of heat in relieving pain and exerting some control in checking these diseases has always been recognized in chronic rheumatic and rheumatoid arthritis; local treatment has comprised hot poultices, compresses, volcanic-mud and moor-mud baths, vapour and hot sand baths, and so on, but the most efficacious of all heat applications is dry radiant heat. Until recently the radiant heat appliances supplied have usually been box-like, the distance of the radiant surface from the joint could not be regulated, and they were often covered in with asbestos sheeting, and thus imperfectly ventilated. In consequence we may have, combined with radiant heat, a condition to be avoided, namely, "moist air heat." They have a more important defect in that, as the radiant surfaces are made of ordinary low candle-power electric carbon filament lamps, they give out rays consisting almost solely of the yellow and yellow-orange. Now the ideal type of radiant heat should be as nearly as possible like sunlight and should give a spectrum ranging from the ultra-red to the ultra-violet. This type of spectrum can apparently be only obtained from lamps of very high candle-power. I am quite convinced that an absence of the violet and ultra-violet rays in the ordinary apparatus is largely responsible for the weakness of sedative effect and slow relief of pain, whereas absence of yellow-green rays may be responsible for only slight stimulation of metabolism.

I find a type of radiant heat apparatus, manufactured and largely used in America,* very satisfactory. It consists of a single large lamp in a funnel-shaped projector lined with a reflecting surface. The projector may be raised or lowered by a system of counter-weights, or

turned in any direction with one hand; the rays can be directed easily and rapidly on any part, and the maximum amount of heat the patient can bear can be adjusted to a nicety. The lamp is very large, with a thick filament, requiring and using up as much current as twenty-four 32-c.p. ordinary lamps. Twenty-four 32-c.p. lamps give out altogether a light equal to 768 candles, consisting almost entirely of yellow and orange rays; the large lamp has a luminosity of only 500 candles; the remaining electric energy, equal to 268 candles, is used up in producing heat rays and the other rays of the spectrum, which, as I have said, are of the greatest value in therapeutic effect. With this apparatus a temperature of 400° F. is obtained, and, as it is a perfectly dry heat, can be endured with fair comfort and without damage to the skin. By the use of coloured glass screens, only red, yellow, or violet rays can, if desired, be used.

The general result of radiant heat exposure for any length of time is that the cutaneous and deeper vessels are dilated, the lymphatics are filled, the local arterial pressure is diminished, and local metabolic processes are increased.

The effects do not pass off at once, and after repeated exposures they become more or less permanent. Besides their influence on the tissues, the rays also exert an effect on micro-organisms, and in addition increase leucocytosis. Thus the condition of circulation and tissue-metabolism in a joint, during and after twenty minutes' exposure to intense radiant heat, is pathologically altogether different from its state before that exposure. The most noticeable result, to the patient, of this altered condition, as a rule, is a rapid total removal or extreme alleviation of pain; probably, the ultra-violet rays, by their anaesthetic action, may be to some extent responsible for this change.

The recent adoption of local ionization as a means of treatment of various diseases has suggested the immediate following up of radiant heat treatment by ionization or cataphoresis with an iodide or salicylate solution. It is an accepted fact that, when a constant current passes through any portion of the body from electrodes soaked with a 2 per cent. solution of any salt (such as lithium iodide or sodium salicylate, for instance), the basic radicle of the salt travels into the tissues from the positive electrode in a more or less direct line towards the negative electrode, whilst the acid radicle leaves the negative pole, enters the tissues, and travels towards the positive electrode in the same direct manner. The quantity of the basic or acid radicle entering is proportional to the current passing, and although the amount flowing in at any period may be comparatively small, yet, if a current of 2 milliamperes per square centimetre is continued for 20 minutes, using large electrodes or a bath of solution, the amount of lithium or iodine entering the tissues in a "nascent" and so very active state, is appreciable. It is probable also that the general migration of all kinds of ions, which takes place along the course of the current, may produce an effect of commotion in and stimulation of the tissues, which is beneficial.

The joints I have treated, as a rule, undergo twenty minutes' exposure to the radiant heat projector at such a distance (the patient often regulating this) that as much heat is applied as can be tolerated. During the sitting the patient moves the joint into different positions, turns it from side to side, and gently rubs the skin with the hand to allay the burning sensation, which passes off fairly rapidly, and is followed, as the heat penetrates the joint, by a sense of comfort and relief from pain, if previously present. When, at the end of twenty minutes, the lamp is switched off, the joint feels burning hot to the touch, and the surface is red and "mottled" from vascular dilatation.

Directly the radiant heat sitting terminates, cataphoresis with iodine "ions" immediately follows; in some cases, however, lithium "ions" seem more efficacious and are used instead. If a wrist is to be treated, it is immersed in an arm-bath containing 2 per cent. lithium iodide solution, and either a large indifferent pad is placed on the back or the other hand is immersed in another arm-bath, ammonium chloride or common salt solution being used for the indifferent pad or bath. If both wrists are affected, I generally ionize one wrist with iodine ions and the other with lithium ions, two arm-baths containing lithium iodide solutions being used, a wrist placed in each and the current

driven from one bath to the other. Where the knee is treated it is packed round with four thicknesses of lint soaked in lithium iodide solution; the lint is in turn surrounded with flexible copper gauze electrodes or by a copper chain-armour electrode; the foot is placed in a bath of sodium chloride solution, for the indifferent electrode. Where one uses baths for feet and hands, large carbon electrodes which are not acted upon by ions are the best, but for knees and elbows one has to use copper electrodes. Any other joint can be treated in a similar manner, but, naturally, the deeper the affected structure from the surface the less is the treatment applicable.

It is necessary to work with large currents; a battery is not suitable to maintain the constant current; one cannot obtain 30 to 70 milliamperes from a battery for long enough even when it is very large and cumbersome. A switch-board, worked from the town electric supply, is perfectly satisfactory, as it enables one to obtain and to regulate to a nicety the amount of current one requires and the patient can bear without pain.

I attach extreme importance to the continuance of drugs by the mouth during the combined treatment, and believe that much less benefit is derived if they are stopped. In my opinion, one great value of cataphoresis is that it causes acid or basic radicles, in a so-called "nascent" state, to be formed in the path of the flow of the constant electric current. Drugs such as iodine preparations or soluble guaiacal salts lying in or circulating through the joint tissues—should the patient have been taking them for some time and in fair quantities—are broken up by the current and locked up in the joint tissues temporarily, instead of being carried through the blood vessels and excreted. Besides, "nascent" ions generally are in all probability much more actively bactericidal and much more energetic than when they combine into soluble non-ionized salts.

I give two examples of cases treated with good results. The number of patients I have had under treatment is naturally small, but all considered themselves improved, and where the pain was a prominent feature relief was well marked. Whether any cases are permanently cured is a matter that only time can show.

CASE I.

Mr. B., aged 48. No family history of gout or rheumatism. Has led a steady life, always athletic, has played much tennis and golf; always in comfortable circumstances, no business or other worries. Has lived in a tropical moist climate for the most part of thirty years, and developed his rheumatic attacks there; they are always very bad of late during the "monsoons," and he has been confined to bed or only able to hobble about during these attacks. Is much better directly he gets home to England. Condition diagnosed as "rheumatoid arthritis" by doctors abroad, as "chronic rheumatoid arthritis" by the London physician who sent him to me.

Present Condition.

Pain and difficulty in moving about, especially in getting downstairs, in both knees and both ankles. Other joints not painful. Cannot walk for any distance without considerable pain. Grating and creaking very marked in both knees and ankles on passive movement; thickening and puffiness of theseoints. Heart and other organs normal.

Treatment.

Radiant heat ten minutes to knee, ten minutes to ankle, followed by cataphoresis for twenty minutes with lithium iodide 2 per cent. solution, 70 milliamperes run between knee and ankle. The right leg had the first treatment; the next day he awoke with "right cold" felt fit for anything, while the left was, of course, the same, and that there was a marked difference between the two, whereas both had been pretty equally bad before." The second treatment was to the left leg, and this made both legs equally comfortable. He continued alternate treatments to right and left legs, and after the tenth was playing golf without ill effect. The grating of the joints has disappeared; he has no pain whatever.

CASE II.

Mrs. A., aged about 35, married, always in excellent circumstances. Family history of gout. The patient had had no rheumatism before present illness, no sore throats. Health always robust, fond of games, played golf until onset of this attack. Has spent much time gardening, her hands being frequently wet and cold. Has lived in a low-lying town which has a very damp subsoil. Rheumatoid arthritis commenced twelve months ago in the proximal interphalangeal joint of the left ring finger; during the first six months it attacked the carpal, carpo-metacarpal, and radio-carpal joints of the right hand, and eventually the left wrist in a similar manner. She was advised to come to Brighton, and forbidden by her London physician to return to her former dwelling. She was placed on

iodides, arsenic, guaiacol, aspirin at various times without much benefit. One feature of her case was the severe paroxysmal pain that came on in the wrists about 3 a.m. and continued till 6 a.m. Radiant heat to the wrists for twenty minutes, followed by twenty minutes lithium iodide 2 per cent. cataphoresis. After the second treatment she had no more night attacks, after suffering from them for three months. She gradually improved very considerably. The pain left her absolutely; the puffiness and swelling of the wrists diminished greatly; she regained power of using her hands for ordinary purposes, but they are still weak.

THE RESTORATION OF VISION IN THE SQUINTING EYE.

By A. ALISON BRADBURN, F.R.C.S.Ed.

OPHTHALMIC SURGEON, ORMSKIRK HOSPITAL AND DISPENSARY, ORKNEY,
SOUTHPORT EDUCATION BOARD.

DURING the past ten years the treatment of squint has made great strides. Formerly glasses alone were prescribed; then supervened the period of promiscuous tenotomies which by their untoward results produced the natural effect of setting back the operative clock until the time had passed for obtaining the best results.

Thanks to the able and painstaking researches of Worth, a scientific line of treatment was evolved out of the chaotic conditions into which matters had got. He showed that a defective cerebral function—named by him the fusion faculty—had a great deal to do with the development of a squint, and that to cure it this faculty required cultivation. Thus it has come to be generally recognized that the presence of a squint is but one sign of other defects, and that the restoration of the normal alignment of the eyes is but a portion of the treatment which a squint requires.

The presence of a squint, in addition to its outward manifestation, nearly always indicates (1) some error of refraction, (2) a defect in the fusion sense, (3) a defect in the vision of the squinting eye, which varies with the age of onset and duration. Therefore the scientific rectification of strabismus includes measures to correct the above. Glasses correct the refractive error, orthoptic exercises or operation remedy the faulty position, training with the amblyoscope overcomes the cerebral defect, and at the same time certain measures can be adopted in some early cases for restoring the defective vision.

Up to the present time we can only completely cure a squint if we get it quite early in life, before a habit of using only the straight eye has resulted in blindness from non-use—amblyopia ex anopsia—in the squinting eye. The limit of age at which such restoration can be accomplished is held to be six years. That such is the fact in the majority there is unfortunately very little doubt, yet that there are exceptions and that such exceptions may perhaps some day prove to be commoner than is at present thought to be the case I think the circumstance I have to report will prove. Excepting congenital cases of blindness in one eye, what right have we to assume that restoration of useful vision cannot be obtained in an organ which as far as we know once performed its full share of duties? If we fail to obtain its restoration of function surely it is more logical to attribute the non-success to the methods adopted than to the materials on which we have to work.

Holding such views, I have for a long time been seeking a method for obtaining what up to the present has been considered impossible of accomplishment, and though at present one cannot produce any very great results, what one has obtained more than justify one in persevering along the same lines.

Worth's amblyoscope was invented by him to overcome the defect in the fusion faculty, by training the brain to recognize the presence of the two pictures which the possession of two eyes affords. Briefly, the method consists in putting before the eyes two pictures, and by increasing the illumination in front of the eye with the defective vision and decreasing that in front of the better (or more used) eye a simultaneous recognition of both is obtained on the brain. Eventually both pictures are recognized under equal illumination and by mechanical means they are superimposed until by degrees they are blended by the brain into one true picture appreciative of depth and perspective. This amounts to the restoration

of what for want of a better term I call "landscape vision," and can be accomplished in a fair number of cases in which amblyopia ex anopsia blindness from non-use has supervened in one eye.

But of what practical use is this "landscape vision" to the patient who in after-life will desire to read, write, or sew with the amblyopic eye? If injury, or operation, or disease supervene in the straight or seeing eye the value of the originally squinting eye will be very little if it cannot be of use in such pursuits. Hence it is obvious that before we can assert we can cure a squint in the fullest sense of the word we must be able to restore to the eye and brain the power to recognize letters and figures. Up to 6 years of age this can be accomplished by the methods so ably laid down by Worth; after this age we must seek other methods. How far this restoration can be accomplished and in what percentage of cases, it is impossible just at present to say, but of this fact there is no doubt that there are a large number of patients with a squint in whom the amblyopia is only latent, and in whom the full, or a very great, restoration of useful vision can be obtained. It has been clearly proved that to leave a squint to be grown out of or until the child is old enough to be operated on is unjust and unscientific, also that the proper course is to adopt amblyoscopic and training exercises as promptly as possible. So now it is just as unscientific to put on one side all attempts to teach the eye to read simply because up to the present no success has attended the efforts made to restore vision in an amblyopic eye. There are cases which are not successful and others which yield gratifying results, and it is impossible, without investigation, to distinguish the two.

The investigation of any case of squint should always include an examination as to presence of the fusion faculty, and in those cases in which it cannot be developed we should not conclude that the monocular visual perceptive centre is incapable of being awakened. If we cannot obtain a blending of the two images, we ought to endeavour to obtain recognition of either picture and then proceed to smaller and smaller objects until printed type can be recognized; in fact, it is not necessary in every case to obtain fusion, it frequently being advisable to use a prism base up before one eye so as to obtain diplopia, and by this means cultivate each visual centre in the brain. We can go further with the use of prisms, and cultivate those other inert portions of the retina in cases where a false macula has become developed, the indications for such developing as the case proceeds.

The case I have to report is as follows:

A youth, aged 11 years, began when about 2 years of age to squint with the right eye, which turned in. Teething was supposed to be the cause. There was no history of any relation having squinted. He was seen by an ophthalmic surgeon at 4 years of age, was given in the right eye $+ .05$ D. sph. and in the left $+ 1$ D. sph. Apparently no attempt was made to test him as to the presence of the fusion sense. He wore the glasses constantly, and was told that the case was proceeding so satisfactorily that in a few years' time he would be able to do without them. The patient was an exceptionally brilliant boy, and at school had taken all his class prizes and had not missed a single day's attendance.

He was brought to me in November, 1907. His right eye turned in about 8° , fixation was possible but slow; the left eye was used in both near and far vision. He was wearing the glasses mentioned, and with them the vision in the left eye was 8 , whilst in the right it was only 4 , with or without glasses. Tests with the amblyoscope showed the vision was distinct in the right eye, but after half an hour's graduation of the illumination recognition of both pictures was obtained, and this was quickly followed by blending.

When seen on December 11th the vision in the right eye was two letters of 5 , and with the amblyoscope true fusion was elicited. In place of the amblyoscopic pictures a set of type-printed letters on transparent sheets of celluloid was inserted. These sheets of printed letters contained two-sized type, larger being equal to letters readable at 3 feet, and the smaller equal to Jaeger No. IV.; these sizes alternated with each other. It was found he could slowly make out the larger letters, but skipped the intervening smaller ones. He was instructed to cover his left eye with his hand when doing his lessons and endeavour to teach his blind eye its letters. At the same time his parents—who most ably co-operated in my endeavours—at my suggestion bought him an alphabet set of letters on pieces of card, with which he built up words with his left eye and then endeavoured to interpret them with the right eye.

December 19th. Fusion exercises of both pictures and type were carried out, and it was found that as the tube in front of the right eye was moved in the direction which brought the letters over the outer portion of the retina they became

suppressed; by therefore adjusting the tube this portion of the retina was exercised.

December 24th. On this date the vision in the right eye had improved to $\frac{2}{5}$, and the ability to take up and maintain fixation was greatly improved.

He was seen once a week, and at each visit exercises were carried out with the pictures and the letters, and by degrees the ability to maintain fusion was cultivated, until he could read type equal to J. 8 and J. 4. For nearly two months very little progress beyond this stage was obtained, and during the time atropine had been used in the fixing eye—the left: this was supplemented by a total-exclusion pad, whilst at the same time he did all his school work with the right eye.

March 20th. Vision in the right eye equal $\frac{2}{5}$ without glasses, and $\frac{3}{5}$ partly with the glasses, but by the end of April he got four letters of $\frac{3}{5}$ vision. During the last six weeks of this period exercises with a 6' prism, base down, had been instituted, and after painstaking efforts we obtained double vision, this being aided by dark glasses at first in front of the left eye.

At the beginning of May the vision in the right eye had risen to four letters of $\frac{3}{5}$ and the shade was removed from the right eye. The removal of the shade, it was feared, would cause the left eye to take up the work of seeing again, but instead the vision of the right eye continued to improve, and when seen last the patient read without his glasses $\frac{3}{5}$ and Jaeger L.

The convergence of the right eye is now all that remains to be removed, and when this is done the condition will be such that he can put his glasses on one side and the vision in both eyes will be equal, his ability to read or write normal, his fusion sense fully developed; in fact, a complete cure will have been accomplished.

This patient, in that he was exceptionally bright mentally, in that there was not much refractive error or any great difference in the refraction of the two eyes, was a particularly suitable subject and justified one in the hope expressed that the lost vision could be restored. But judging by others, far less suitable cases, which have

proved as far as they have gone capable of great improvement, there seems good reasons for hoping that after all we may be able to remove the last stumbling-block which remains in the treatment of squint.

During the course of exercises with the printed type a very interesting feature showed itself. By some authorities it is held that a certain portion of the brain controls a horizontal section of the centre of the visual field. Now, as this case improved it was noted that the lines of letters running across the centre of the visual field were the earliest to become recognized, the lines in the upper and lower parts of the field of the same size type developing later. In the stages of development it was noted that the intermediate letters were not seen, every alternate letter, no matter its size, being recognized. As improvement took place this skipping of letters became less and less in the horizontal line in the visual field, whilst it still remained in the upper and lower fields. This interesting feature, I think, confirms the theory of the function of the cerebral visual centre, and, moreover, tends to show that these cases of acquired amblyopia are due to a cerebral and only partly a retinal defect.

The accompanying illustration is that of an instrument which Messrs. Armstrong, of Deansgate, Manchester, and Bold Street, Liverpool, have brought out for me. It consists of a series of cards and a holder, and is intended to be used at home by the patient. On each card are printed letters in two sizes, so arranged that a small and large letter alternate. Each card has progressively a smaller size of type, the smallest being composed of 5-point type. When the instrument is held by the handle in front of the face, the two prisms opposite the eyes produce a vertical separation of the image of the card held at the far end of the instrument. Thus, in normal eyes an image of the card is presented to each eye. In the case of a patient

who has by non-use forgotten how to use one eye the card belonging to the amblyopic eye will only show the large letters; the intervening smaller letter will be unrecognized. To elucidate this feature the normal eye must be covered and the patient asked to read the letters he sees. When the correct card is in position the patient will "stutter" over the smaller type. Under such circumstances the other should be momentarily uncovered, by which means he will recognize the letter correctly. Then on re-covering this eye the patient should endeavour to see the letter by his amblyopic eye. Such recognition will not be instantaneous nor for some time permanent. The patient has to teach his receptive perception centre to remember the letter just as he teaches and cultivates his "memory" for pictures, poetry, prose, history, dates, etc. As soon as one card is mastered the next smaller is similarly dealt with until they all are mastered. When one endeavours to train an amblyopic eye by means of a single picture of letters any mistakes in naming of letters has to be corrected by word of mouth, that is, the patient learns the nature of the image presented to his brain by means of the auditory channels. With my instrument he learns by means of the optic nerves and visual centres, which seems a sounder and more rational method. The use of this instrument, in addition to enabling the patient to practise at home, enables the trainer when the patient comes for the other lessons to examine by means of the card for evidence of progress and for proofs of attendance to one's injunctions regarding the carrying out of the exercises at home.

PERSISTENT THYMUS AND SUDDEN DEATH.

By SIDNEY HERBERT DAUKES, M.B., B.C. CANTAB.,

BECREHAM

THERE is no greater check to the progress of therapeutic knowledge than that which comes from a too ready acceptance of the value of a remedy because in an isolated instance that remedy has seemed to be successful. Remembering that this applies also to many other instances of cause and effect, I submit this case, which I consider of interest not only to the medical but also to the legal mind, with a full realization of the possibility that I have overestimated the importance of the local condition.

At midnight on July 25th I was called to a case of supposed murder. The history I will relate as nearly as possible from the evidence placed before the magistrates, and subsequently before Mr. Justice Ridley at the Maidstone Assizes.

Late on the evening of July 25th a man named H. entered the room where his children slept. Finding that his wife was out he was heard by a neighbour living in an adjoining room to mutter threats against the absent woman. Subsequently the latter entered the house and a scuffle occurred in the passage, but no sounds were heard betokening blows or in any way significant of extreme violence. A few seconds later Mrs. H. rushed out in a state of extreme terror. She tried to get into a house opposite, but failed as the door was shut. She then ran down the road with her husband in pursuit, about four yards behind. Suddenly she seemed to collapse; her legs gave way, and she fell to the ground "like a dead thing." All witnesses are agreed upon this point—it was not a stumble, she was not touched by anybody, she fell, as another witness put it—"all of a heap," and never moved or uttered a sound again. Her husband, who had been drinking heavily, rushed up and, using a violent threat, told her to get up. As she did not move he is said to have kicked her "in the left side." Three women bear witness to this fact, whilst a fourth witness denies that any kick was given. A point which seems to have struck many who heard the evidence, and one which fixed itself in my mind with overwhelming force, was that the woman was dead when she fell, and that, if her husband did kick, he kicked her dead body. The body was then carried indoors, and it was there that I first saw it.

A careful external examination of the body revealed only one mark of any importance—namely, a bruise on the extensor surface of the left forearm. It might have been caused by the fall or it might have been the result of the

kick; in either case I consider that it was inflicted after death. There was no bleeding from ears, nose, or mouth, and no orbital haemorrhage. The necropsy took place eighteen hours after death, and, needless to say, was done with extreme care.

Necropsy.

The body is that of a well-nourished and apparently healthy woman. Rigor mortis well marked. Recent bruise on extensor surface of the left forearm; old burn on dorsum of right hand; old scratch on dorsum of left hand; small bruise on ulnar surface of right forearm; old scar over right breast. Hypostasis well marked. Signs of incipient putrefaction in right iliac region and round umbilicus. No injury to scalp or face. No blood in ears, mouth, or nose. Mouth and throat normal. No glandular enlargement.

Skull.—No sign of fracture. Meninges normal. No meningeal haemorrhage. Cerebrum, cerebellum, pons, and medulla normal. No signs of concussion.

Thorax.—On removing sternum the great vessels and upper part of pericardium were found to be covered by a thymus gland $2\frac{1}{2}$ in. long, 2 in. wide, and weighing 1½ oz. Pericardial and pleural cavities normal; no adhesions and no haemorrhage. Heart—muscle healthy, valves healthy; weight, 8½ oz. Aorta and great vessels, normal. Lungs, normal.

Abdomen.—Peritoneal cavity, normal; no haemorrhage. Liver, normal, 64 oz. Spleen, normal, no rupture, 6½ oz. Pancreas, normal. Kidneys, normal; capsules strip readily. Suprarenals, normal. Uterus and appendages, normal; not menstruating. Bladder, normal. Stomach, no disease; contained half-digested food. Intestines, lymphoid tissue seemed to be rather prominent, otherwise normal.

This autopsy well agreed with the past history of the woman, who seems to have been exceptionally healthy. She had two children, both healthy.

The only conclusion which I could come to, having heard all the evidence, was that the woman died from excitement, mental and physical, causing heart failure; the persistent thymus being in some way a predisposing factor.

The thymus gland seems to reach its maximum size at two years, at which time its weight is about 200 grains (400 grains would be an exceptional weight). The gland generally maintains its size from the second to the eighth year, from which time it gradually atrophies, becoming practically non-existent by the time adult life is reached.

For some time the association between an abnormal persistence of this gland and sudden death, induced by trivial causes, has been recognized. Cases are reported by Fowler of death during the administration of a hypodermic injection, death during an examination with the aid of a spatula death during light anaesthesia, death during bathing, and death from a superficial burn by a hot-water bottle. In all of the cases mentioned a persistent thymus was found.

In the case which I report an emotion—namely, fear, together with some physical exertion—seems to have determined the fatal result, without any actual violence.

How the gland can have such an adverse influence upon an otherwise healthy body is difficult to conceive.

It is easy to theorize upon the subject; to give an anatomical explanation and say that the close relationship of the gland to the trachea, vagi, and great vessels, affords a clue to the situation; or, again, to give a physiological explanation and say that an internal secretion, which produces a sudden fall of blood pressure, is the determining factor.

A mechanical explanation seems totally inadequate in such a case as I have recorded; and should the persistence of the gland be a danger to those who are its unfortunate possessors, I am inclined to think that the explanation is more likely to be found in the physiology, than in the anatomy, of the gland.

I have been told by an eminent authority on anatomy that the condition of persistent thymus is not altogether uncommon in the female sex. It does not seem to me, however, that this fact in any way negatives the possibility of its malign action in certain cases. In one way it lends support to the idea, as these rather obscure cases of sudden death are far more common in women than in men. Mitral stenosis is a common defect, but it is only in a small proportion of cases that it leads to sudden death.

In conclusion, whatever cause may be allotted to the case in question, I think that the subject of sudden death associated with persistence of the thymus gland—quite apart from the condition known as status lymphaticus—is worthy of the attention of those skilled in medical jurisprudence.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TRAUMATIC RUPTURE OF SPLEEN.

E. V., aged 11, was admitted into the South Devon and East Cornwall Hospital, Plymouth, at 10 p.m. on June 22nd, with a history of having jumped from a low wall ten hours previously, missed his footing, and fallen with his belly on a large stone placed across the gutter in a country road.

He appeared in considerable pain, and his abdomen was very hard and rigid, so that nothing could be made out by palpation. There was a superficial abrasion over the left hypochondrium. The pulse was 120, rapid and running; temperature 98°. There was slight dullness in the left flank.

Twelve hours after the accident I opened the abdomen in the middle line above the umbilicus, when some dark liquid blood escaped, and on exploring with the fingers in the splenic region blood could be felt flowing. The left rectus was divided transversely half-way across, to give more room, and the spleen was brought up without much difficulty. It was torn nearly across, its whole surface lacerated, so that suturing or plugging appeared equally futile; it was bleeding freely. The pedicle was clamped, the organ cut away, and the stump transfixed and ligatured. The effused blood was rapidly removed, as far as possible, and the wound closed. No injury to other organs was apparent.

The boy recovered satisfactorily and went out in a month. A blood count by Dr. Pethybridge on his departure showed: Reds 5,200,000, whites 7,400, haemoglobin 70 per cent. I saw him a week or so ago—quite well, to all appearance.

The point of interest was the very little on which to base a diagnosis—practically only the skin abrasion and the slight dullness. He complained of general abdominal pain, and, though the spleen was thought to have been ruptured, the abdominal rigidity only permitted some "catastrophe" to be inferred with absolute certainty. Delay in operation might have been followed by a different result, as the haemorrhage must have gone on steadily.

C. E. RUSSEL RENDLE, F.R.C.S. Edin.,

Assistant Surgeon, South Devon and East Cornwall Hospital.

EUCAIN AND ADRENALIN AS AN ADJUNCT TO GENERAL ANAESTHESIA IN OPERATIONS FOR HAEMORRHOIDS.

THE necessity for complete relaxation of the sphincter in these cases requires the administration of general anaesthetics to a dangerous degree, and demands very constant watchfulness on the part of the anaesthetist, in order to maintain this condition during the whole period of the operation. To paralyse the sphincter without rupturing some of its fibres entails a good deal of force and some judgement. Without an anaesthetist who has had a good deal of experience in this variety of operation, much embarrassment to the operator may occur, owing to the contraction of the sphincter preventing a clear exposure of the area of operation, especially if the requisite dilatation of this muscle has not been procured.

In doing some operations for interno-external piles under eucain I noticed the great ease with which the sphincter could be dilated, and that it remained quite painless during the operation. It occurred to me that the use of this drug would be of great assistance if combined with general anaesthesia, and I have lately tried it; 10 c.cm. of Barker's solution is injected into the external sphincter on each side of the median raphe, the needle being inserted in the middle line and pushed into the muscle in an outward direction. This is done fifteen minutes before the general anaesthetic is commenced, and by the time the patient is under, the sphincter will be found quite paralysed. It has been found possible to complete the operation under very light anaesthesia—such a degree, in fact, as would be quite useless without previous injection of eucain and adrenalin.

I have been much struck by the comparative absence of pain after the operation—due, I presume, to absence of bruising and tearing of the sphincter. The lessened amount of anaesthetic which is inhaled by the patient

must also contribute to a more rapid return to his normal condition and lessen the anxiety which must occur to both operator and anaesthetist, especially when dealing with private patients.

F. J. W. PORTER, Major, R.A.M.C.

Colchester.

POISONING BY CYLLIN IN AN INFANT.

On August 21st, 1908, an infant of 13 months was admitted into Wrexham Infirmary, having drunk, about twenty minutes before admission, a certain quantity of cyllin. The exact amount taken is unknown, but, according to the infant's mother, it was not much. The mother had been using it for disinfecting some articles used by her husband, who had just been removed from the house with typhoid fever, and, having left the bottle of cyllin on the chair, the child had got hold of it when her back was turned.

On admission the infant was quite unconscious, both conjunctival reflexes absent, the pupils equal, but slightly dilated. There was a strong odour of cyllin in the breath and slight corrosion of the lips. The face was very pallid. Voluntary movements were absent. Apomorphine $\frac{1}{2}$ grain was injected hypodermically, and the stomach tube introduced. The stomach was washed out with warm water. The tube being withdrawn, the infant vomited; the vomited matter looked like undigested food, but smelling strongly of cyllin. The respirations became very slow, cyanosis became very marked, both lips and ears being quite livid. Simultaneously the pulse was becoming feebler and more irregular, till almost impalpable. The respirations had almost ceased, and the heart's action was almost arrested; $\frac{1}{2}$ grain of strychnine was given hypodermically, and artificial respiration applied. After five minutes the respirations improved, the lips became redder, and the pulse stronger. Vomiting recurred. The stomach tube was again introduced, and the organ washed out with warm albumen water. The cyanosis, dyspnoea, cardiac irregularity reappeared, so that the tube was withdrawn, and artificial respiration again started. In a short time the heart recovered, and the respirations improved, but artificial respiration had to be kept up for three hours to prevent relapse, by which time the infant began to open its eyes, make voluntary movements, and show signs of consciousness. For the next three days the pulse was rapid, the temperature 100.6°, and the infant was kept on milk and soup. After this it regained its normal state.

ADAM N. ROBERTSON,

Junior House-Surgeon, Albert Dock Hospital.

ADHESION OF SOFT PALATE TO NASOPHARYNX.

Two children, aged 6 and 11 respectively, were sent to me by the medical inspector of schools, with a note stating that they were suffering from "adenoids." From the appearance of the children I quite agreed with the diagnosis. Neither of them could breathe through the nostrils, and both had every sign of the "adenoid face."

I had them up for operation next morning. On examination under anaesthesia not a trace of adenoids was found. There was not even thickening over the pterygoids. What I did find was a complete adhesion between the naso-pharynx and the soft palate. I tried to get a Gotstein curette up behind the soft palate, but could not force a passage. Ultimately I broke down the adhesions with my finger and made a clean sweep. The haemorrhage was considerable, but the result was eminently satisfactory. The sensation conveyed to the finger was very similar to that by an adherent placenta. Neither of the children had any enlargement of the tonsils. I have had many "nose and throat" cases, but have never before met with any condition such as I have described.

I have looked up all my textbooks, and not one of them mentions a case of the soft palate and posterior nares being adherent. The cause of the condition is not clear, but it occurred to me that it was probably congenital.

ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

REMOVAL OF LARGE RENAL CALCULUS: RECOVERY.

(By H. BRUNTON ANGUS, M.S., F.R.C.S., Honorary Surgeon.)
J. T., aged 56, a miner, was admitted under my care on July 14th, 1908, complaining of pain in the right loin.

History and Diagnosis.

For six years on several occasions he had had pains in the "small of the back," not confined to either side. A year before admission the pain became localized in the right loin, radiating into the right iliac region, and sometimes shooting down to the right testicle. It was so bad that it doubled him up, and sweat stood in drops on

his forehead; vomiting occurred during two attacks. For twelve months also there had been frequency of micturition, but he had never noticed blood in the urine. Twenty-six years ago he passed a piece of gravel the size of a pea. A radiograph showed the presence of a large calculus in the right loin.

Operation.

On July 17th, 1908, the ordinary oblique incision between the last rib and the iliac crest was made and the right kidney exposed. The pelvis of the kidney was seen to be distended, and a hard body could be felt through the wall. The pelvis was incised in the direction of the ureter and the calculus removed. The pelvis of the kidney was greatly hypertrophied to accommodate the stone; the kidney was little enlarged and seemed quite healthy. A purse-string of medium catgut was passed round the opening in the pelvis, keeping outside the cavity, and tied tightly. The wound was drained with rubber tube and the parietes united with interrupted catgut sutures, silk-worm gut being used for the skin.

Subsequent Progress.

The wound healed without any leakage of urine, and the man got quite well.

Specimen.

The stone, reddish-brown and rough, is suggestive of oxalate of lime, but as it has not been sectioned I cannot give the composition. It weighs 6½ oz., is rounded, and comes to a conical point where it projected into the ureter. As the size is unusual, I should like to hear if there is any calculus of larger size removed from the same situation in the museums of our British hospitals. It is interesting to notice that the kidney was not disorganized, but the pelvis had evidently grown with the stone which it accommodated, and urine must have passed all the time.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Friday, December 18th, 1908.

Sir PATRICK MANSON in the Chair.

The Rat-flea Theory of Plague.

DR. HOSSACK, of Calcutta, in a paper on the rat-flea theory of plague, said the position he was about to take up was diametrically opposed to generally accepted ideas, but his theory, though somewhat revolutionary, was based upon practice and observation, which alone could give the information that was wanted. The investigation of disease was generally futile when observers started with preconceived ideas as to its pathology, and much of the work that had been done on plague was open to this criticism. Since Patton's well-known experiments the rat flea theory had held the field, but it had now advanced far beyond the limit which these experiments or any others justified. If one began with the fixed idea that the rat flea was the principal agent in the transmission of plague, it was astonishing how many circumstances would be found to corroborate that view. Thus, the prevalence of plague was often found to correspond to the rat population, to the numbers of rat fleas, to the breeding seasons, to alleged preferential species of rats, and to many other things. But if one tested experimentally those statements it would be found that practically the whole of them were contrary to facts. It had, for instance, been said that the difference in the ratio of infection in Bombay and Calcutta corresponded to the relative differences in numbers of *Mus rattus* and *Mus decumanus*. As a matter of fact a recent rat census had shown that statement to be quite incorrect. Again, as to seasonal prevalence, both species of rats bred all the year round. Besides this there was no preferential species; *decumanus* was as susceptible to plague as *rattus*. In the Punjab, there were no *Mus rattus* at all, and they knew what had been the experience there with regard to plague. The theory advanced in the third report of the Commission that *Mus rattus* was ten days later in developing the disease was also unsupported by facts; and if the figures were looked into it would be seen that the illustrative charts do not correspond with the experimental data on which they are constructed. The Commission had also endeavoured to establish a "climatic plague temperature." The limit they gave was wide enough, namely, 85° F. to 50° F.; but even that appeared to be insufficient, for 100 per cent. of their own transmission experiments had been successful at 40°, and 70 per cent. at 90°. Clinical experience, indeed, was that plague has no preferential temperature. It was also the case that Calcutta was characterized by remarkable freedom from human fleas (*Pulex irritans*). On the other hand, dog fleas were abundant; rat fleas, again, were seldom or never found in Calcutta. Experiment and observation showed that most of the received ideas on the habits and life-history of rat and other fleas were wrong, for they were based on the assumption that fleas were evenly distributed. On the contrary, there was an extraordinary variation in the prevalence of different species of fleas in different parts of India. Statements, for instance, that light caused fleas to leave their hosts, or that they preferentially bit at night, were also incorrect. As to the important question, Does the rat flea bite man? the evidence that the rat flea had a strong distaste for the skin of man was conclusive. In conditions which were natural—more so than those of the Commission's experiments—only 1 in 6 attempts to induce rat fleas to bite the human skin was successful. Another point was that in acutely infected houses—say, houses in which 15 or 20 cases of plague had occurred—instead of swarms of rat fleas being found, none were seen, although they were carefully searched for. His conclusions were, first, that the rat flea, when starved, will not bite man at all; and, secondly, that when starved he does so very unwillingly. On the whole, the facts he had adduced as to the flea population rendered any idea of its active agency absolutely impossible. He could not conclude without

acknowledging the courtesy and kindness which he had received from many fellow-workers, who took an entirely different view of the etiology of plague.

Sir PATRICK MANSON confessed that on reading the reports of the Commission he had been convinced of the truth of the rat-flea theory; but after hearing Dr. Hossack's paper most of them would make up their minds to doubt.

Dr. G. FORD PETRIE said that he had the honour to take part in the work of the Indian Plague Commission, and as they knew, that body took an entirely different view to that of Dr. Hossack. Their position was that, although they did not deny the possibility of other methods of infection, the thing that mattered was the agency of the rat flea. There were abundant statistics to show the exact route of infection both in rats and in man. Of 5,000 dead rats picked up in plague houses, 72 per cent. had buboes in the neck, but no mesenteric buboes; of rats fed by infected material, only 36 per cent. had neck buboes. He thought that the experiments of the Commission, if carefully considered, fully proved that intestinal infection, as between rats, very rarely occurs. Rats, for instance, did not eat the dead bodies of their comrades. On the whole, he considered that the evidence that rat fleas were the essential method of transmission from rat to rat was conclusive. There was abundant proof, also, that in a man the route of infection was essentially the same. Skin abrasions in guinea-pigs—and they were about the most susceptible animals—rubbed by human secretions in which plague bacilli were swarming, hardly ever admitted the pathogenic organism. The facts that attendants in plague hospitals did not get plague, and that guinea-pigs placed in infected bedding were also immune, were highly significant. The experiments of the Austrian Commission had made it clear that infection takes place in the great majority of cases through the punctured skin, and at the Mabratta Plague Hospital in Bombay Dr. Choksy had shown that human infection is very rarely effected by the alimentary tract. The intestinal contents of the rat flea contained millions of plague bacilli, while in the excreta of the rat they were comparatively few in number. Again, the prevalence of plague at different places corresponded accurately with the rat-flea census; and still more was this true of the seasonal prevalence. Thus at Poona and Belgium, where plague annually broke out badly in July and August, and at Bombay, where it did so in January, it had been found that the numbers of rat fleas closely corresponded to the case incidence at those seasons.

Sir HAVELOCK CHARLES said that the statistics which had been brought forward on both sides of the question were quite convincing, and the ordinary man was in consequence much puzzled as to what was the actual position. It was, however, the case that the association between rats and plague was invariable in India; nobody disputed that; and, taking everything into consideration, fleas presumably had a good deal to do with transmission. It had struck him that perhaps this was not a new theory; and that the plague which was conveyed by the Ark of the Covenant to Ashdod, Gath and Ekron was possibly transmitted by the fleas in the badgers' skins with which, they were informed, the Ark was covered.

Dr. G. C. LOW asked why Dr. Petrie laid so much stress on the position of the buboes. Why should one expect mesenteric buboes in feeding experiments? Was infection not possible through the mucous membrane of the neck or throat? He would also like to know the method which was employed in making these accurate counts of fleas.

Mr. CANTLIE said that the possibility of transmission from man to man direct had been neglected. Experience on the Gold Coast, in Glasgow, and in other places, showed that pneumonic cases of plague might be very common and that there might be no rat infection at all.

Dr. HOSSACK, in reply, said that the proportion of pneumonic plague in Bombay was only about 1 per cent., but that in other districts it was sometimes very prevalent, and might indeed form the whole epidemic. No doubt that was mostly direct infection. They counted fleas by chloroforming the animals on which they were living. The fleas were affected by the anaesthetic, and could be easily combed out and counted.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Friday, December 4th, 1908.

W. G. SMITH, M.D., President, in the Chair.

Lupus Mutilans.

THE PRESIDENT showed a case of lupus mutilans, pointing out some unusual features: (a) Two symmetrical patches of ordinary lupus on the face, one on either cheek. Nodular lupus was rarely symmetrical on the face. (b) Lupus on the conjunctiva of upper and lower eyelids of both eyes. This had not spread from the adjacent skin or up the nasal duct. (c) Notable involvement of the soft parts of the fingers with deformity. (d) Changes in the bones of the digital phalanges, as shown by the x-ray photographs.

Habit Spasm.

Dr. COLEMAN exhibited a young girl who, two months before, on going to drill in an institution of which she was an inmate, noticed her right arm moving. The movement had continued ever since, except when she was asleep. It was regular, and at 160 to 180 to the minute. There was some loss of power, and the movement was intensified by resistance, and overflowed slightly into the right leg. There was nothing special in her family history, but he had found that the patient had been in the habit of using a sweeping brush, and the spasm was not unlike that movement. Similar cases had been recorded in which the movement had persisted for some time, and he took it to be hysterical in origin.

Persistent Ductus Arteriosus.

Dr. COLEMAN exhibited a girl, aged 15, who had never suffered from any special symptoms except dyspnoea on the slightest exertion. She had always been fragile, but had no special sickness in reference to her heart. She was admitted to hospital about a fortnight previously, complaining for the first time of pain in the region of the heart, which passed off in two or three days, leaving her as well as usual. On physical examination it was found that the impulse beat was in the mammary line in the fifth space and somewhat diffuse, and on palpation a remarkable thrill was noticed in the second and third left intercostal spaces. Another more abrupt impulse was felt opposite the third left space at the edge of the sternum, which coincided with the second sound. There was a very remarkable thrill along the left border of the sternum, which began immediately after systole, and extended almost up to the next systole. On auscultation a very loud murmur was heard, the maximum intensity being in the second intercostal space about an inch to the left of the margin of the sternum. The time of this murmur was late systolic. It persisted for a considerable time into diastole, and was heard as a practically continuous murmur up to the next first sound. There was no cyanosis, but the state of the blood was as in congenital heart disease. Some cases identified as persistent ductus arteriosus by Dr. Gibson, of Edinburgh, were identical with the signs in the present case. The intensified pulmonary second sound heard low down was very remarkable. It was not heard during every heart beat; it was generally present, but sometimes it was absent for a few beats. There was no clubbing of the fingers.

A Case of Cretinism.

Dr. MOORHEAD exhibited a case of cretinism—a girl, aged 7½ years. She had weighed 4 st., and under thyroid treatment went down in about three weeks to 2 st. 8½ lb. The weight had been almost steady since. On diminishing the dose the child became irritable, and apparently was going back. The actual dose now being given was 10 grains of thyroid extract daily. That was above the dose generally recommended, but he had found an immediate improvement in the mental symptoms on 6 grains a day. The actual improvement for the last three months had been remarkably slow. The PRESIDENT said the condition had become extremely rare in the British Isles, and they were not very well able to fix its pathological boundaries. It was associated at one time with enormously large thyroids and at another time with atrophied thyroids. Dr. COLEMAN was inclined to think that sporadic cretinism was not so very uncommon, as he had seen four cases during the past twelve or fifteen years.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ANAESTHETICS.

At a meeting on December 9th, 1908, Mr. RICHARD GILL, President, in the chair, Dr. N. H. ALCOCK read a paper on fifty cases anaesthetized with known percentages of chloroform. The chloroform-laden air was supplied to the patient on the plenum system by the special apparatus devised by him, and described in our issue for August 15th, 1908. Dr. BLUMFELD considered the apparatus of special value for teaching purposes, and thought that every hospital should have an inhaler of this pattern, in order that students might learn something about the percentage of chloroform vapour required to produce the different stages of anaesthesia in varying types of patients. Mr. COLLIER referred in detail to some of the cases that he had anaesthetized by this method, which he considered most interesting and scientific, but he complained that in its present form it was too bulky and noisy to become popular. The instrument, moreover, required the assistance of a second person to pump the bellows, unless an electric motor were used. The latter was expensive and very heavy to carry about. He agreed with Dr. Alcock as to the remarkably large percentage of chloroform vapour usually required to satisfactorily anaesthetize fat patients, and mentioned one case in particular to emphasize this point. Dr. BEAUMONT said that he had noticed more after-sickness with this apparatus than when the open method was employed; and he ascribed the difficulty in the case of obese subjects to emphysema. In his reply, Dr. ALCOCK said he was at present endeavouring to remedy the faults pointed out by Mr. COLLIER. The increased after-sickness he thought must be a mere coincidence. The absolute accuracy of the apparatus could be depended upon, and oxygen could be used instead of air if desired. This was of great service in certain cases. Specimens of the inhaler, of various sizes and patterns, were shown. One was fitted with a foot-bellows, one with an electric motor to drive the air through the chloroform chamber, and one with an oxygen cylinder. The apparatus was also shown in section, so that the inner working of the instrument could be more thoroughly understood.

SECTION OF DISEASES OF CHILDREN.

At a meeting on December 18th, 1909, Dr. PORTER PARKINSON, in opening a discussion on *Whooping-cough*, pointed out that in England the death-rate per million from this disease had diminished of late years, from 527 per million in the years 1861-70 to 450 in the years 1881-90, and in 1895 to 316. It is more fatal in Scotland than in England; less so in Ireland. The contagion must be a specific organism, but had not yet been isolated with any certainty. The infection is conveyed by the sputum, which was said to be most virulent during the catarrhal and early paroxysmal stages. The virus remained active after drying for at least several weeks, as had been proved by epidemics arising on board ship where no other source was probable. It was easy to overlook the primary disease when bronchitis or pneumonia supervened, as the characteristic whoop then frequently disappeared. In respect of treatment, bromoform was recommended, with the warning that it should be dispensed in solution one drop to an ounce of water with a few drops of alcohol, 1 to 6 drachms being given in a dose. Dr. L. GUTHRIE, in referring to the history of whooping-cough, mentioned the term "chin-cough" as being still used in some parts of the country. It was derived from the name "la quintana," or "tussis quintana," by which the disease was known in Paris in 1578. The paroxysms being believed to occur every five hours. Bromide and belladonna were his favourite drugs for relieving the symptoms. Dr. WALTER CARR said that as regards prognosis, early manifestations were no guide to the subsequent severity of the disease. In treatment he regarded pure fresh air, at a temperature of about 60° F., as very important. If the child's temperature was 100° F. or over it should be kept in bed. He had tried various vapours and fumes, but was doubtful of their efficacy. He believed that bromide of potassium had a value, and in rubbing the child with a liniment. There was danger of upsetting the intestinal canal with over-drugging. When vomiting was pronounced, hyd. cum creta and bicarbonate of soda and rhubarb often did good.

When a child was vomiting constantly it was well to give a little food to bring on a paroxysm, and then after the vomiting to give more food, which would frequently be retained. Dr. J. D. ROLLESTON said that from 1899 to 1907 131,830 cases were admitted to the Metropolitan Asylums Board Hospitals, and of these 756, or 0.5 per cent., were suffering from whooping-cough. Another 855, or 0.6 per cent., subsequently developed whooping-cough as a complication. Of 55,557 cases of diphtheria, 340, that is, 0.5 per cent., were suffering from whooping-cough, and another 0.4 per cent. developed it as a complication. Whooping-cough had not any very unfavourable influence on the acute cases of infectious disease with which it was associated. Troussseau had remarked that the paroxysms of whooping-cough disappeared during scarlet fever, but his own experience did not confirm this. Dr. EWART pointed out the serious effects which frequently follow whooping-cough in children. He had often seen relief follow the instillation of oil into the nostrils. Patients should be placed in the best conditions for resistance, and should live in fresh warmed, but not over-dry, air. Iodide of potassium was of value, and he believed in the inhalation of terebene and its use in a liniment. A respiratory belt, as advocated by Kilner, was also good. Dr. MILNER BURGESS pointed out that only two papers on whooping-cough were included in the reports of the Society for the Study of Disease in Children. Very little had been added to the subject during the last eight years. In an experience of thirty years he only remembered one case of meningeal hæmorrhage, and he asked why it was so infrequent. In respect to treatment he laid stress on very careful dieting with liquid food in small quantities, given immediately after a paroxysm. Dr. J. H. FRANCIS NUNN said that many children died from cerebral conditions due to the fits of coughing. He agreed that the diagnosis from the paroxysmal cough of influenza was sometimes very difficult. He reminded members of the old fashioned method of sending patients to the gasworks to inhale the vapour, and recommended that the child should be placed in a room with the gas jet turned on for a quarter of an hour. Dr. RUSSELL WELLS said that some French observers said that cases were only infectious during the catarrhal stage, and he was in favour of this view. Whooping-cough presented a characteristic symptom complex, which had led the speaker some years ago to think that the part affected must be different from that occurring in the ordinary cold. He thought that the symptoms were due to an effect on the nerves produced by a toxin secreted by the microbe. He regarded the symptoms of whooping-cough as due to an increased excitability of that part of the nervous system concerned with the vagi, and with this view had administered cocaine by the mouth, the dose being on the basis of a grain three times a day for an adult. He had never seen evil effects follow, and in children there was little danger of forming a habit. The results were often remarkable, the disease being greatly diminished and then abolished. Dr. J. BRENNACKI spoke with some favour of the plan of taking children to the gas-works, but wondered whether the benefit was due to the waste products there or to the gas. Dr. LEOPOLD GOFFE advocated syringing the ears twice or thrice daily with boric lotion and then painting the external auditory meatus and membrana tympani with a strong solution of cocaine. The formula was: Cocaine hydrochlor. 23 grains, liquor hydrarg. perchlor. 20 minims, glycerine 5 drachms, water 4 drachms. Dr. E. I. SPRIGGS, in answer to the question raised by Dr. Milner Burgess as to why meningeal hæmorrhage was so rare, pointed out that experiment during muscular exertion had shown how well healthy vessels could sustain a sudden rise of pressure without giving way. Dr. BERNARD BAILEY said that experience in the Children's Hospital, Shadwell, showed that the disease was not infective after six weeks' whooping. Dr. MEREDITH RICHARDS thought that the major amount of infection was in the early catarrhal stage. His practice was to exclude children from elementary schools for five weeks, and to exclude contacts for one month. Dr. GEORGE CARPENTER referred to 466 cases seen as out-patients, the majority of which were below the elementary school age. It was important to cleanse the naso-pharynx, and if necessary to operate on it. Four of his cases developed the whooping habit, which persisted for many years after the disease. Mr. R. CLEMENT LUCAS showed a young man who presented

deformity of the chest and dwarfing in stature, as a sequence of whooping-cough at the age of 4 years. He was 21 years of age, only 5 ft. in height, and weighed 6 st. 10 lb. The thorax below the level of the nipples on both sides was deeply depressed as the result of the collapse of the lung in childhood, whilst above that level the chest was fairly developed. He had enjoyed good health up to the time of the attack of whooping-cough. Owing to the diminished lung capacity, he suffered from dyspnoea on exertion and found a difficulty in mounting stairs.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—At a meeting on December 9th, 1908, Dr. MICHELL CLARKE, President, in the chair, Mr. A. L. FLEMMING, in a paper on *Post-anaesthetic vomiting*, recorded conclusions based on observation of 500 consecutive cases anaesthetized at the Bristol Royal Infirmary. The proportion of cases in which vomiting occurred as the immediate result of the anaesthetic could be materially reduced by allowing only milk to be taken prior to the operation and entirely avoiding beef-tea; also by guarding against movement of the patient during the induction and in the course of anaesthesia. Rolling of the patient from side to side during operation or subsequent bandaging was a frequent cause of vomiting. For inducing anaesthesia he recommended the use of gas and ether combined during the first twenty minutes, followed by the administration of chloroform and ether from separate bottles if prolonged anaesthesia were required. Post-operative bronchitis and pneumonia were usually due to inhalation of vomited matter by the unconscious patient. The methods he described had reduced the percentage of patients vomiting after recovering consciousness to 5 per cent. Dr. J. SWAN agreed that movement should be avoided; pneumonia due to inhalation of vomited material was, as a rule, not the fault of the anaesthetist. It might often be prevented by washing out the stomach before the operation. Mr. S. V. SROCK said he endorsed the value of substituting milk feeds for beef-tea before operation. Prolonged fasting was bad. A sister at a children's ward had remarked to him that occasionally children preparing for operation refused to take the milk feed during the morning before operation, and such children nearly all vomited; only a small proportion vomited of those who took the milk. Lavage of the stomach would not always prevent vomiting if the operation were protracted; he would always wash out the stomach before, rather than after, the patient was anaesthetized. Mr. HEY GROVES said that movement of the patient could not always be avoided, the "fear of the table" made it necessary in some cases to administer the anaesthetic elsewhere than on the operating table. Patients did not vomit until the anaesthetic was stopped, so they should be kept fully anaesthetized until the bandaging was finished and the patient returned to bed. Mr. PAUL BRUSH suggested that the patient should be anaesthetized in an adjoining room upon the actual operating table, which could then be wheeled into the theatre. Dr. SYMES maintained that the duration of the operation influenced the frequency of vomiting, which was the result not only of the drug administered, but also of the nervous shock. This shock was proportional in some measure to the length of the operation; moreover, nervous people often experienced nausea and even vomiting after administration of nitrous oxide. Two drugs—morphine and atropine—administered in water before the operation appeared each to lessen vomiting. Dr. BERTRAM ROGERS inquired whether the various commercial methods of preparing chloroform or ether could be said to affect vomiting. Dr. OGILVY drew attention to the proneness of ophthalmic cases to vomit during the course of operation. Dr. FORTESCUE-BURCKDALE remarked that beef-tea stimulated gastric secretion, and would on that account be more likely to contribute to vomiting than milk. Mr. LACE quoted the experience of a colleague who had found that the administration of nothing but peptonized milk for twenty-four hours before operation diminished the chances of anaesthetic vomiting; and on inquiry he had found a consensus of opinion among nurses to the same effect. Mr. FLEMMING, in reply, said that preliminary lavage of the stomach sometimes gave the anaesthetist a false sense of security; in faecal vomiting it was useless, for during a long operation regurgitation into the stomach provided

fresh material to be vomited. The suggestion of anaesthetizing patients on the operating table would only affect the vomiting during induction of anaesthesia. He objected to the preliminary use of morphine and atropine on account of the difficulties they introduced during anaesthesia. As to the use of acetone chloroform, he thought that, with the addition of sufficient ethyl chloride to render the evaporation point stable, it was a safe anaesthetic, but he preferred to administer a preparation about which there was no doubt. Mr. HEY GROVES read a paper on *Three cases of ileo-colostomy*. From the success in these cases he was persuaded that the operation was at times of great value, although occasionally the antiperistaltic wave which normally occurred in the ascending and transverse colon gave rise to painful distension in the occluded portion of bowel. The other communications included a paper on *Barley itch*, in which Dr. W. KENNETH WILLS described a pruriginous eruption seen in dock-workers engaged in the unloading of certain varieties of barley; it was due probably to the presence of "Cowhage" (*Mucuna pruriens*) among the barley, although he had also found an acarus, not the *Sarcoptes hominis*, present in some samples.

LIVERPOOL MEDICAL INSTITUTION.—At a pathological meeting on December 10th, 1908, Mr. T. H. BICKERTON, President, in the chair, the following were among the exhibits:—Mr. NEWBOLT: (1) Carcinoma of transverse colon in a woman aged 40; perforation had taken place. Excision of the growth with pelvic drainage and secondary end-to-end suture resulted in recovery. (2) Volvulus of caecum causing intestinal obstruction in a male aged 60; the caecum was excised and the bowel drained. The patient died on the fourth day. (3) Two specimens of sloughing intestine excised in cases of strangulated herniae: immediate end-to-end suture was done in both cases successfully. (4) Malignant growth of the sigmoid causing intestinal obstruction in a male aged 32. The growth was brought outside the abdomen and colotomy performed; secondary resection and end-to-end suture was done later. Mr. FRANK JEANS: A gall stone which had caused gangrene of the bowel 1 in. from the ileo-caecal valve. Peritonitis was present; the history resembled that of a perforated appendix. Mr. R. W. MURRAY: A case of Paget's disease of the nipple of three years' duration. Dr. BLAIR BELL: (1) A hypernephroma. (2) Uterus didelphys from a patient aged 21. Each uterine body lay in an inguinal sac. Radical cure was done on each side, the right tube and ovary being returned to the abdomen. Mr. THELWALL THOMAS and Dr. MURRAY BLYTH: (1) A neuro-fibroma of the posterior tibial nerve from a female aged 51; it was of slow growth, and full of soft myxomatous tissue. (2) A lobulated tumour removed from beneath the gluteus maximus of a female aged 56. The patient gave a history of three months' duration. (3) A "mole" from the face of a farmer aged 75. It had existed for twelve months but had rapidly increased in size recently. Dr. W. B. WARRINGTON read a note on the more recent physiological experiments upon the cerebellum. He stated the views of Herbert Spencer, Hughlings Jackson, and others, and demonstrated the connexion between the physiology of this organ and symptomatology. He illustrated his paper with numerous diagrams showing the anatomical connexions of the cerebellum.

MIDLAND MEDICAL SOCIETY.—At a meeting held on December 16th, 1908, Professor GILBERT EARLING, President, in the chair, Mr. NUTHALL showed a man who had sustained a *Penetrating wound of the heart*. Whilst pulling a barge nearer the canal side the heavy boathook he was using slipped and came into violent contact with his chest as he was leaning forward. A large splinter penetrated into and broke off in his chest. He seized the protruding portion and wrenched out a piece some 6 in. in length, but feeling acute pain he came to the hospital. Seen half an hour after the accident he evinced acute dyspnoea. A foreign body could be seen and felt projecting under the skin over the third left intercostal space. The entry puncture was situated 1½ in. below the centre of the left clavicle. On cutting on to the splinter it was found to have entered the chest through the third left

space; and to have passed into the pericardial sac. The track was enlarged and the splinter followed into the pericardial sac. The splinter was drawn out. Three and a half inches had entered the pericardium, the whole piece being 5½ in. long. There was no pneumothorax. A condition of pleuropneumonia without effusion complicated the after-progress to recovery. The man was now, six months after the accident, about to resume work. Mr. J. FUNEAUX JORDAN showed two specimens of *Ovarian tumour*. The patient in the first case, aged 38, had on August 9th a six months miscarriage, after which her doctor found a small tumour in the lower left part of the abdomen. In four weeks this small tumour had grown rapidly, rising well above the umbilicus and filling up the left side of the abdomen and partly the right. In the second case, a doctor found a small tumour in the pelvis of a woman aged 53. A month later it had grown to a large median tumour, rising as high as an inch above the umbilicus, and was removed. The first specimen proved to be microscopically a most malignant carcinoma, the second a multilocular cyst, the cavities lined by a regular layer of large goblet cells, and filled with mucinoid material. The first patient already showed signs of a recurrence of the growth in the peritoneum; the second one was in perfect health. Dr. O. J. KAUFFMANN showed specimens from a case of *Acetonaemia*. The patient was a woman aged 20. She had suffered for five years from symptoms closely resembling those of gastric ulcer, including haematemesis. Shortly after admission into hospital diacuturia and acetonuria were discovered. The patient then had sudden severe symptoms suggesting perforation of the ulcer, and under chloroform an emergency laparotomy was at once done, but no perforation was found, nor was any evidence of gastric ulcer to be seen. Ninety hours after the laparotomy the patient died, having vomited frequently, blood once, and having gradually become comatose. The urine subsequent to the operation had become scanty, and the last few specimens had been devoid alike of aceto-acetic acid and acetone. The liver weighed only 36 oz., and showed intense fatty infiltration; the kidneys showed scarring, but no trace of interstitial or subcapsular nephritis. There was also some fatty infiltration of the tubular epithelium. The heart showed only some fibrosis, no fatty change. There had been no ulcer either in the stomach or duodenum. Death was attributed to the acetonaemia, due, in the first place, to some indefinite digestive disturbance, and intensified by the chloroform; in other words, delayed chloroform poisoning in an acetonaemic individual.

HARVEIAN SOCIETY OF LONDON.—At a meeting on December 10th, Dr. CHARLES BUTTAR, Vice-President, in the chair, Dr. VICTOR BONNEY, in a paper on the bearings of pathology on the prevention, diagnosis, and treatment of carcinoma of the cervix, said that out of 1,876 cases investigated at the Middlesex Hospital Cancer Research Laboratories no less than 1,796 were in women who had been married, and only 9 per cent. had not borne children. Clinically a case in an undoubted virgin was almost unknown. Every case of carcinoma of the cervix appeared to be founded on a chronic cervicitis plus some unknown additional factor. The incidence of the disease might, perhaps, be lessened by greater attention to the hygiene of the cervix and vagina in married life, in which connexion habitual vaginal douching was to be commended. From the pathological point of view the surgery of the disease was quite hopeful. No less than 55 per cent. of persons dying of carcinoma of the cervix exhibited no metastatic growths whatever, whilst in the case of the breast only 65 per cent. so escaped. The track of lymphatic permeation was very simple, straight out through the parametrium to the external iliac glands. The bladder and rectum were involved by the much slower process of infiltration. The operation popularized by Wertheim satisfied the demands of pathology, and was destined to become the only operation performed for the cure of the disease. Improved technique had greatly reduced its mortality. It was especially suitable for early cases. The speaker and Dr. Comyns Berkeley had now performed twenty of these operations, mostly in advanced cases, with four deaths.

Rebivus.

PROBLEMS OF THE NOSE.

"If you see a head, hit it," was the Irishman's injunction at Donnybrook Fair. The modern textbook on rhinology is more helpful; it tells you in how many different ways this injunction—so far as the nasal septum is concerned—may be carried out. Dr. GLEASON, in his *Manual of Diseases of the Nose, Throat, and Ear*,¹ mentions nine operations which have been devised for the correction of deviation of the nasal septum. With a pardonable patriotism, the operations which he has mentioned are for the most part those devised by American surgeons, and naturally include the one devised by himself, a description of which we are glad to read in the author's own words. In addition to these, he gives Dr. Ballenger's own description of his technique of performing the so-called "window resection" operation of the deviated area, which Dr. Gleason tells us "was advocated first by Ingals, and later by Krieg," adding that "Killian removes the cartilage and bone of the entire deviated area, preserving the mucous membrane of both sides of the septum." This list of ten could easily be increased to a dozen or even two dozen operations which have been devised for the same purpose. We are reminded of an apt remark made by Dr. Gleason's compatriot, Dr. John N. Mackenzie of Baltimore, in an address at a meeting of the American Laryngological Association in 1904: "Even a partial list of the operations performed on the septum would rival in length the catalogue of the ships in the Iliad, or the genealogical records of Deukemon." Be that as it may—again to quote Dr. Mackenzie—"no single method is applicable to all cases, and it will sometimes be necessary to resort to several different procedures in individual cases before the deformity is overcome." In the present day it is commonly conceded that abnormal conditions of the nose and of the naso-pharynx are important factors in causing deafness and disease of the ears. Dr. Gleason has devoted to this important subject a chapter which is evidently the outcome of experience. It is carefully written, and illustrates very well how only those who are actually engaged in the practice of otology are in a position to express a useful opinion on what has been at times a debatable subject. In this, as in every other textbook of the kind, there are points open to criticism, but taken as a whole the author has undoubtedly achieved his object, which was to supply to students and general practitioners a manual with the essential facts of rhinology, laryngology, and otology in as concise a form as possible. The book is compactly printed and well bound, and with its limp leather cover and red edges presents outside the appearance of what it is inside—a concise concordance of the subjects it deals with.

The appearance of Dr. LEO KATZ's monograph on the diseases of the nasal septum and their treatment² is further evidence of the fact that the nose is receiving in the present day that prominence which nature intended it should always enjoy. Dr. Katz treats of his subject in twelve chapters. The first six are concerned with anatomical considerations, methods of examination and the production of anaesthesia of the nasal septum, as well as the deformities of that structure and their correction; the last part of the book deals with the diseases and new growths met with in this region. The entire monograph occupies 170 royal octavo pages, and a proper sense of proportion is observed in the amount of space allotted to the several chapters. In discussing the treatment of deviation of the septum he gives preference to the submucous resection operation as performed by Professor Killian. Brief mention is also made of methods devised by other authorities—amongst them that by Asch, one of the pioneers in this work, whose name we note throughout is incorrectly spelt. In an age unparalleled for wealth and variety of instruments designed to attack the nasal

septum, it is a pleasure to read Dr. Katz's observation ancient this point that "In der Beschränkung zeigt sich erst der Meister."

Dr. DE HAVILLAND HALL's textbook on *Diseases of the Nose and Throat* has during the past fifteen years introduced so many students and practitioners to the study of rhinology and laryngology, that it is quite unnecessary for us to dwell upon its general merits and utility. Mr. HERBERT TILLEY, who assisted Dr. Hall in writing the second edition, tells us in the preface that when the time arrived to consider the question of this, the third edition,³ Dr. Hall desired to be relieved of all responsibility in the work, and with reluctance Mr. Tilley finally consented. That the old order is changing and yielding place to new, and calling for new editions of books on rhinology, is borne in upon us by the "passing" of Bellocq's cannula. It seems but yesterday that students were led to believe that the whole range of nasal surgery was comprised within a knowledge of the use of the polypus forceps, and of an instrument which bore the name of Bellocq, and that a lack of knowledge of how to manipulate the latter upon the day of reckoning might be materially to their disadvantage. Even if Bellocq's cannula still survives as a test of knowledge for examination purposes, it is disappearing from the practical textbooks. In the last edition of the book before us its doom was foretold, and no mention is made of it in the present edition. Mr. Tilley reminds us that the book is "intended to form one of a *Practical Series*, and consequently symptoms, diagnosis, and treatment are more fully discussed than debatable matters relating to the etiology and pathology of the various diseases of the nose and throat." Here we are disposed to join issue with Mr. Tilley. The discussions held from time to time, and more recently those in the Odontological and Laryngological Sections during the meeting of the British Medical Association at Sheffield, would lead us to believe that the treatment of at least one of the diseases of the nose—namely, suppurative within the antrum of Highmore—is a very debatable subject indeed, and that the pathology of that disease has been really more neglected than debated. In a textbook intended for the use of students attention to the etiology and pathology as conducive to a better understanding of the treatment of disease might have been more insisted upon. Dr. Charles Bolton has considerably added to the value of the work from the standpoint of the medical practitioner by his article on diphtheria and the throat affections of the acute specific fevers. A new feature of this edition is a chapter dealing with certain practical points in the anatomy and physiology of the nasal cavities. Additional space is given to a description and treatment of the diseases of the accessory sinuses. Photographs and diagrams of these regions undoubtedly lend themselves to book-making, and many new plates have been introduced. By the insertion of some of these illustrations into the text and by a compression of the type the book might have been kept more nearly to its original dimensions and at the same time made more portable and more readable without detracting from its practical value. Mr. Tilley has made it quite clear to his readers that operations undertaken for diseases of the frontal sinus may be attended with complications of a very serious nature, and with commendable courage he has introduced a plate illustrating osteomyelitis of the skull resulting from septic infection of the diploe after operation on the frontal sinus from one of his own cases. One cannot close the book without the reflection that, at least in the matter of the frontal sinus, operations are not to be undertaken lightly, and in the less severe cases perhaps after all it would be better to use an extra pocket-handkerchief a day than be a dead man for the rest of one's life.

Of the many bony cells and cavities from which otologists and rhinologists have to evacuate pus, there is not one which causes them more anxious thought than the frontal sinus. The complications of inflammation within the frontal sinus, which may occur not only before but after the sinus has been opened by an external operation, form the subject of a monograph by Professor P. H. GERBER of

¹ *A Manual of Diseases of the Nose, Throat, and Ear*. By E. B. Gleason, M.D., LL.D. Philadelphia and London: W. B. Saunders and Co. 1907. (Post 8vo, pp. 556. Illustrated. 12s.)

² *Die Krankheiten der Nasensecheidewand und ihre Behandlung*. Von Dr. Leo Katz. Mit 8 Tafeln und 34 Abbildungen im Text. Würzburg: Curt Kabitzsch (A. Stuber's Verlag). 1908. (8vo, roy. 8vo, pp. 180. M. 6.80.)

³ *Diseases of the Nose and Throat*. By Herbert Tilley, B.S. London: F. & S. Eng. London: H. K. Lewis. 1908. (Demy 8vo, pp. 552. 12 illustrations. 14s.)

Königsberg.⁴ These complications are a *bête noire* well known to every rhinologist, and yet textbooks on diseases of the nose barely touch the fringe of this subject. When it has been stated that Professor Gerber's monograph covers 450 royal octavo pages of closely-printed matter in which the author strictly adheres to the title of his subject, and in which space is nowhere trespassed upon by descriptions of operations with their accompanying illustrations, it becomes unnecessary to enlarge upon the importance of the subject, or to emphasize the serious consideration which it deserves. From the standpoint of the surgeon the complications and their treatment completely overshadow the disease itself, and from the standpoint of the practitioner who has to weigh the *pros* and *cons*, and bear some responsibility in advising his patient either against an operation or to incur the risks of an external operation on the sinus, a knowledge of the complications is of more value than a textbook description of the operation itself. The descriptions of these operations, together with the figures and plates illustrative of the instruments and the technique which bulk so largely in textbooks on rhinology, might usefully be suppressed or curtailed to make room for information more useful, if not so alluring, to the practitioner. Professor Gerber's monograph has taken over five years to produce, and he is to be warmly congratulated upon its completion. It is not possible here to do more than give the general scope and scheme of the work. The osseous changes, both pathological and developmental, naturally occupy a large amount of space, in fact, about one-fourth of the book, and chapters on the anatomy and morbid histology follow. The paths of infection and the bacteriology of the disease receive careful consideration. In the next 200 pages the intracranial complications are treated. The book concludes with a chapter on the prophylaxis of the complications, the indications, the dangers of the operations, and a critique on the fatal operation cases. At the end of each chapter there is a very full bibliography, and the points raised in the chapters are illustrated by cases. By no means the least valuable part of the book is the tabular matter of typical cases collected from the literature, they make Dr. Gerber's work a complete compendium of our knowledge of the subject, and our sense of gratitude is only intensified by the thought of the amount of time and of patient literary research the work has called for. Dr. Gerber has rendered a considerable service, it is to be hoped, in more ways than one by the publication of this monograph. It will not deter experienced rhinologists from opening the frontal sinus when circumstances render such a procedure imperative. Moreover, it is not intended to do so; "mein Thema," writes the author, "sind die komplizierten Stirnhöhleuentzündungen, die operiert werden müssen." A careful perusal of the work cannot fail to raise for serious consideration the all-important question when the frontal sinus should be opened. "How often has the frontal sinus been opened to find little or nothing pathological in its interior is a question," says Dr. John N. Mackenzie in the address from which we have already quoted, "that never will be answered." It is not uncommon while still in his apprenticeship days, and even before he has completed the manuscript of that textbook on the subject which he has chosen for his special department of practice, that the young man's fancy lightly turns to thoughts of opening the frontal sinus. Should his eyes happen to fall upon one of the sentences on the last page of Professor Gerber's book—perhaps it would be as well not to translate it—"Zum mindesten sollen wir die probatorische Eröffnung der Stirnhöhle nicht scheuen"—it is to be hoped that he will also read the subsequent lines: "Nein! Ich habe nicht zu viel operiert! Auch hier Zahlen für Worte! Ich habe etwa 500 Stirnhöhleentzündungen gesehen und davon 80 operiert, d. i. 16 Prozent. Ich habe gegen 80 Prozent Heilungen. Ich habe keinen Todesfall." It is to be hoped further that he will have the courage to publish his fatal cases; a glance at the last table in Dr. Gerber's book will at once convince him that in so doing he will be in the most excellent company.

The basis of Dr. BRADEN KYLE'S *Textbook of Diseases of the Nose and Throat*,⁵ which has now reached its fourth edition, is pathology. This in itself constitutes a sufficient claim to recognition. The author tells us in his preface that it has been his "aim to give in full the etiology and pathology of the various diseases, so that by this detailed description treatment is indicated and easily directed." The book will do this and more. It will check an empiricism which begets recruits for that "fraternity of carpenters," for whose higher education Dr. Braden Kyle's compatriot, Dr. John N. Mackenzie, so earnestly pleaded before the American Medical Association. In a word, Dr. Braden Kyle credits his readers with some power for deductive reasoning, and appeals to it. The natural laryngologist of to-day, impatient for results, only too ready to accept rather than to investigate, with a desire to please or a desire to cloak, is apt to sledge his powers for deductive reasoning, and to fall back upon the Herr-Professor hat gesagt line of argument. Whilst readily conceding that in the matter of experience age brings with it a certain something that nothing else can bring, it is as well to remember that even a Herr Professor who has not paid attention to pathology may arrive at erroneous conclusions drawn from his own clinical impressions—pure empiricism. The appearance of a textbook on diseases of the nose and throat in which so much attention is drawn to the etiology and pathology of the diseases is a sign of the times, and a most welcome sign. In Dr. Braden Kyle's work those seductive diagrams of surgical achievements of which we are all so weary have been left on one side to make room for some excellent plates and figures illustrating the morbid anatomy and histology of the diseases. Whilst the general plan and arrangement of previous editions have been adhered to, the book has been thoroughly revised, and many entirely new articles have been added. The book is well printed, well bound, and well illustrated; moreover, it has an index which is remarkably complete. For the experienced it will be a work for ready reference, while on the inexperienced it will create a good impression and cause the subject to be viewed from a scientific standpoint.

PREGNANCY AND APPENDICITIS.

RENNALL'S work on appendicitis during pregnancy and labour⁶ is one of a long series of monographs of high scientific value, inspired by the teaching of Professor Otto Engström. They stamp the University of Helsingfors as one of the best centres of medical teaching in the world, in spite of its disadvantages. These disadvantages are, first, the use of a language unintelligible to most civilized people; Dr. Engström's pupils get over this by writing in German. Secondly, the liability to interference by stupid military officials. We hope that the Russian Government may gradually come to see that the best thing for Finland is to leave it alone, and let it govern itself, as it was doing so well in 1897, when some of the English members of the International Medical Congress visited that enlightened country—the intellectual jewel of the Russian Empire.

The book before us is one of the best monographs on its subject that has yet appeared. The author has been laborious in his search after material, and comes to sane and wise conclusions. It has been stated that appendicitis in pregnancy is commoner than is generally supposed, and the inference follows that pregnancy in some way favours appendicitis. Our author points out that the months during which a woman is carrying a child within her form only a small part of her life, and that therefore if her appendix is so constructed as to give trouble, the chances are in favour of the trouble coming when she is not pregnant. That appendicitis with pregnancy has been more frequently reported in recent years is accounted for by the spreading of knowledge as to the diagnosis and treatment of that disease. It has been said that pregnancy favours the occurrence of appendicitis, and increases its dangers, by the pressure of the enlarging uterus, the lifting up of the pelvic peritoneum, and dragging upon adhesions. Rennall points out that if this were so appendicitis should be

⁴ A *Textbook of Diseases of the Nose and Throat*. By Dr. Braden Kyle, A.M., M.D. Fourth edition. Philadelphia and London: W. B. Saunders Company, 1907. (Med. 8vo, pp. 725, 215 illustrations. 18s.)

⁵ *Über Appendicitis während Schwangerschaft und Geburt*. Von Gerhard Rennall. Aus der Gynäkologischen Klinik von Professor Dr. Otto Engström in Helsingfors. Berlin: S. Karger, 1903. (Sup. Roy. 8vo, pp. 119. M. 4.)

⁶ *Die Komplikationen der Stirnhöhleuentzündungen. Beiträge zur Anatomie, Pathologie und Klinik der Stirnhöhle*. Von Dr. P. H. Gopfer. Berlin: S. Karger, 1903. (Sup. roy. 8vo, pp. 466. 36 Abbildungen. M. 15.)

especially frequent in the later months, when these effects are at their height. He gives an analysis of over 160 cases, and shows that appendicitis is as common before the uterus has risen out of the pelvis as it is later. When the appendix has been inflamed it is not in every case adherent to the uterus. Such pressure or pulling as the enlarging gravid uterus may exert is very gradual and gentle. Renvall's general conclusion is that pregnancy neither favours nor hinders the occurrence of appendicitis, either primary or recurrent; nor, if such illness occurs, does pregnancy appreciably affect the severity or duration of the disease. But it cannot be denied that if localized suppuration round the appendix is present at the time of labour, the sudden diminution in the size of the uterus after delivery (as well as other influences acting at that time) may lead to the breaking down of adhesions, and to a local peritonitis becoming general.

The diagnosis of appendicitis is a little more difficult during pregnancy than in ordinary conditions, because the lifting up of the pelvic peritoneum and the tension of the abdominal wall make palpation less certain; a patient who is near the end of pregnancy is apt to take for the beginning of labour pain which is really due to a different cause.

There is difference of opinion as to the treatment of appendicitis in pregnancy. Some French surgeons have expressed what many will think extravagant views; and urged operation in every case and as early as possible. Dr. Renvall seems to us here very sensible. He says acute appendicitis in pregnancy is to be treated according to the accepted principles of surgery: a careful consideration of all the features of the case, and intervention when the symptoms become threatening. The only difference that he would make is that in a recurrent attack during pregnancy he would operate sooner than in the case of a patient not pregnant, so as to prevent possible complications in childbirth. Some persons have urged that whenever acute appendicitis requiring operation occurs during pregnancy the uterus ought to be at once emptied. Dr. Renvall holds that cases must be differentiated. The surgeon may have to do with (1) an encapsuled abscess, or (2) diffuse peritonitis. (1) If an encapsuled abscess is present there is now abundant evidence that it can be successfully treated without interfering with the pregnancy. Forced delivery is in such cases injurious rather than beneficial; it robs the patient of her prospect of a living child, and even if there is reason to think that a child is dead, it inflicts on her two operations instead of one. (2) If diffuse peritonitis is present the treatment indicated is to drain the peritoneum, and this can be more efficiently done if the uterus has been emptied. Here, therefore, speedy delivery is called for. If there is much meteorism it is impossible to drain the peritoneum without it. But, he adds, individual cases may call for exceptional treatment.

After laying down the very sane and temperate propositions that we have quoted, the author reports 25 hitherto unpublished cases, 23 of which were observed in the clinic of Professor Engström and reported by the author. The other two were under the care of Professor Krogius, and have been communicated to the author by friends. Then follow abstracts of 253 published cases, and after that a large but not complete list of literary references.

We regard this monograph as one of the best contributions to our knowledge of a difficult subject that has yet appeared. It does its author the greatest credit. We congratulate Professor Engström on having a pupil and follower so intelligent, industrious, and sensible.

TEXTBOOKS OF HYGIENE.

The Manual of Hygiene, which was brought out by the late Dr. Edmund A. Parkes forty years ago, always held its own, not only as a textbook for students, but also as a book for reference; and successive editors, including Professor de Chaumont and Colonel Lane Nutter, kept up its reputation in these respects. In 1896 Colonel Nutter and Colonel R. H. Firth, while retaining the general scheme adopted by Parkes, to a great extent rewrote the work, and altered the title to *The Theory and Practice of Hygiene*. The third edition of this book has now been very extensively revised by Colonel Firth, the revisions being so

extensive as to render the work almost a new one.⁷ A rearrangement of the section dealing with sanitary law has added very much to the value of the book for purposes of reference. At the end of each section the law relating to the subject of the particular section is given in some detail. For example, the law relating to bakehouses is given in the chapter upon food, and in the chapter on water there is a summary of the Acts of Parliament relating to water supplies. The chapter upon sanitary administration is for the most part reliable, though one or two slips have been made. The statistical tables given on pages 17 and 18, which, it is stated, are those required to be appended to the annual reports of medical officers of health, have not been in use since 1900, and no mention is made of the excellent Table V, relating to infantile mortality, which has been in use since 1905. It is a pity, too, that the copy of the annual memorandum issued by the Medical Officer of the Local Government Board, with respect to the annual reports of medical officers of health, should not have been of more recent date. That given on page 13 was issued in 1904, and does not contain any reference to the need of inspecting and reporting upon public elementary schools, to which special reference was made by the Board's medical officer in 1906 and 1907. When discussing the utility of isolation hospitals, Colonel Firth admits that it is very difficult to demonstrate the precise effect of isolation hospitals, either upon scarlet fever or any other kindred disease, by means of statistics, which require a large amount of qualification before they can be of any value for comparative purposes. He points out that if an attempt is to be made to express in figures the effect of the isolation of scarlet fever or any other disease in special hospitals, the attack-rate should be expressed not in the terms of the entire population but of those exposed to infection. He expresses the opinion that so far as mere statistics are concerned the case is not proven that isolation hospitals have brought about no reduction in the incidence of scarlet fever, and he very properly asks whether it is wise to apply statistics to a problem of which none of the factors are constant, and where there is a varying host, a varying parasite, and, in some instances a varying age-grouping of the population. The views of the author upon the much-debated question as to whether isolation hospitals should be permanent or temporary buildings will meet with the approval of most of those who hold that isolation is necessary. He considers that all administrative arrangements and a certain limited accommodation for the sick should be in permanent buildings, which can be quickly supplemented if need be in times of epidemic. The various methods of disinfection are dealt with in an exhaustive manner. The different types of steam disinfectors are accurately described and their capabilities are very fairly estimated. No mention is made, however, of the method of disinfecting books suggested by Dr. Symons, of Bath, in which they are placed in a steam disinfectant fitted with a vacuum apparatus; at a point in the oven most distant from this apparatus formalin is placed in a vaporizer, and formic aldehyde and steam are liberated at about 80° C. as the pressure inside the machine is reduced. A clear and concise account is given of the Rideal-Walker method of testing the strength of disinfectants, and although the drop method is criticized, the opinion is expressed that with modifications it may constitute the simplest procedure in standardizing disinfectants. With the establishment of a special sanitary service both in the regular army and in the Territorial Forces, much more regard will have to be given to military hygiene than has hitherto been the case. Colonel Firth devotes one of the longest chapters in the book to this subject, which he treats in a practical and masterly manner. The section upon the hygiene of camps should be studied by all those who are likely to be called upon to advise the military authorities as to the provision of sites for camps or as to their conduct when established.

It is just eighteen years since Dr. B. A. WHITELEGGE brought out his textbook on *Hygiene and Public Health*, of which there were subsequently issued nine editions. In 1905 Dr. GEORGE NEWMAN assisted in the compilation of

⁷ *The Theory and Practice of Hygiene*. (Nutter and Firth.) Revised by R. H. Firth. Third Edition. London: J. and A. Churchill, 1908 (Roy. 8vo, pp. 1002. 21s.)

the tenth edition, and an eleventh edition by the same authors is now before us.⁸ The general arrangement is the same as in former editions. One noticeable feature of this manual is the inclusion in its pages of the text of important regulations and instructions from the Local Government Board and other Government departments. The majority of medical officers of health are in private practice and are not provided with an office in which official documents can be properly indexed and produced at a moment's notice, so that it is of the greatest service to them to be able to find copies of such documents gathered together in one book. At the present time, when the duties of the district medical officer of health and those of the newly-appointed school medical officer are not too well defined, the former will find an advantage to refer to the latest memorandum of the Local Government Board concerning his duties with respect to schools and infectious disease, and he will receive a great deal of assistance from the perusal of the regulations laid down by the Education Committee of the London County Council with respect to infectious diseases in elementary schools. The authors have set out both these documents at length and have commented on some of their provisions. The carefulness with which the revision for this edition has been carried out is apparent on every page, so that it is all the more surprising to find even a qualified approval given to the privy-midden system of excreta removal. It ought to be clearly pointed out on p. 249 that ashes are sterile, and that a privy midden without any structural alteration may be made into an inoffensive earth closet by throwing on to the excreta a sufficient supply of dry earth, "ordinary mould being the best owing to its richness in nitrifying organisms."

NOTES ON BOOKS.

EVERY fresh edition of *The Medical Directory*⁹ inevitably contains a certain amount of additional matter, but in spite of this its publishers, Messrs. J. and A. Churchill, usually contrive to avoid material increase of weight. This is of some importance to those who have to handle this invaluable volume frequently, and in the edition for 1903 they have been completely successful in this respect. The total number of names in the directory is now nearly 40,000—in precise figures 39,992—exclusive of those in the list of graduates and licentiates in dental surgery. This is an increase of 289 over last year, but a smaller increase than usual. Indeed, for the past five years the number of additional entries has been steadily falling. In most respects the distribution of the contained names is much the same as in former years, but there are one or two interesting differences. Thus the London list, in spite of the growth in the general total of names, shows a falling off, only 6,420 names appearing in it, as against 6,550 last year. Similarly, the list for Ireland shows 2,656 names, which is 4 less than in the edition for 1908. In each of the other lists, however, there is a greater or smaller growth: nevertheless the provincial list for England still overtops the total of the lists for Wales, Scotland, Ireland, practitioners resident abroad, and the Naval, Military, and Indian Medical Services, all put together. Only in course of time can errors in a work of this description be discovered: but from an experience of many years' daily use it is safe to conclude that if any errors exist they are few and unimportant. We notice that the abstract of the principal laws affecting the medical profession, which is the work of Mr. R. G. Glenn, LL.B., has this year been revised by Mr. W. Oliver Hodges, and that it is well up to date.

The volume recording the Transactions of the American Proctologic Society at its tenth annual meeting is not very bulky, but contains several communications of considerable interest. In this respect the palm should, perhaps, be awarded to the discussion on the choice of an anaesthetic for use during operations on the rectum, small and great, which was introduced by Dr. J. M. Lynch, of New York. From the address of the President, Dr. A. Bennett Cooke, it would appear that rectal surgery claims in America the position of a speciality and that it is held in increasing esteem.

Those familiar with French but not with German and desirous of studying Schmidt's work on morbid conditions

of the gastro-intestinal tract,¹⁰ both functional and organic, may be glad to know that a translation by Dr. R. S. Kolbe is now available. It appears to be an accurate version of the original, and the methods recommended by Schmidt for the determination of the extent to which digestion and absorption are complete are all clearly described. The translation is adorned by some twenty woodcuts and three coloured plates.

The second volume of the *Archives of the Pathological Institute of the London Hospital*¹¹ contains ten articles on cases of special interest to the morbid anatomist and histologist. Drs. Turnbull and Worthington discuss regeneration of the liver and describe three cases illustrating the transition from regeneration to carcinoma in cirrhosis of this organ. They find that there are two elements in the liver capable of independent regeneration, namely, the cells of the lobules and the interlobular bile ducts. In two of these cases a typical regeneration of the liver cells led to the formation of cancer, and in the third, cancer was due to an aberration of the regenerative process in the bile ducts. Amongst other articles of special interest may be noted one by Dr. Turnbull on the formation of bone and marrow in the suprarenal capsule, a discussion of mesoarteritis and aneurysm by Dr. Aitchison, and the description by Dr. C. H. Miller of a case of general lymphatic hyperplasia.

As an addition to the ordinary guide-books, but not in any way replacing them, a little work, *Six Weeks and the Mediterranean*,¹² may prove exceedingly useful. There are many persons of limited leisure intending a trip to the Mediterranean who would wish to spend the time at their disposal to the best advantage. As a help in this direction the present work can be recommended. How well planned was the trip described will be gathered from the fact that in addition to calling at Gibraltar and Algiers, it allowed of one day being spent at Genoa, four days at Naples, seven hours at Messina, eighteen hours at the Piræus, eleven hours at Smyrna, and a day at Constantinople. The fortnight spent in Egypt was sufficient to afford several days in Cairo and a trip up the Nile as far as Luxor. On the return journey time allowed of several hours being spent at both Naples and Marseilles. It would seem difficult to improve upon the scheme of this trip as regards the variety and interest of the places visited in the short space of six weeks. The author writes clearly and well, and his book is profusely illustrated with excellent photographs: these last, indeed, are worth considerably more than the modest sum charged for the little work.

MEDICAL AND SURGICAL APPLIANCES.

A Syringe for Intramuscular Injections.

DR. HENRY FITZGIBBON, M.D., sends the following description of an all-glass syringe with stopper: I have now been for upwards of thirty years Visiting Surgeon to the Government Westmoreland Lock Hospital in Dublin, and during that extended period I have resorted, both in hospital and private practice, to all of the various recognized methods of treating syphilis, and of late years in all suitable cases I select to treat uncomplicated cases by intermuscular injections of mercurial cream prepared according to the formula given by Colonel F. J. Lambkin at page 26 in his book on the treatment of syphilis, published in 1905. I have now treated a very large number of cases by this method, with most satisfactory results as to apparent complete and rapid cure, and with absolute immunity from any local or constitutional disturbance whatever beyond the rare occurrence of a temporary painful nodule at the point of injection: when this has happened it was due to either a portion of the cream leaking back into the subcutaneous tissue between the nozzle and the skin, or to my having omitted to massage the part sufficiently at the time of the injection. The cream I use is especially prepared by Mr. J. I. Bernard, 26, Clare Street, Dublin. He dispenses the drug in glass tubes, each of which contains about 40 minims, equivalent to eight doses of 5 drops each. These tubes are a complete safeguard against precipitation of the mercury, as they are hermetically corked and absolutely full: their contents are easily transferred into an all-glass syringe without any

loss by means of a glass piston-rod supplied with each box for the purpose. I have designed an improvement upon the all-glass syringes hitherto in use, which, when only one or more injections have been made from it, enables it to be converted into a perfectly air-tight reservoir for the preservation of what remains in it free from atmospheric deterioration or pollution of any kind until it is required again for use. This is accomplished by replacing the

ment to those parts as I instructed them. Mr. Beaton, 14, England's Lane, Belsize Park, N.W., has kindly made the instrument for me.

BRITISH MEDICAL BENEVOLENT FUND.

At the December (1908) meeting of the committee twenty-three applications were received, and sums amounting to £205 voted in relief, six cases being passed over. Appended is an abstract of the cases assisted:

1. Daughters, aged 50 and 34, of late M.R.C.S., L.S.A. For the last ten years have been compelled to nurse their invalid father, an annuitant of this Fund and of Epson College; are now endeavouring to obtain employment. Voted £20.
2. Daughter, aged 29, of late M.R.C.S., L.S.A. Is unfitted for anything but housework, and is one of several sisters just left quite unprovided for. Voted £10.
3. Widow, aged 68, of M.D. Quite unprovided for at husband's death, and unable to any longer obtain post as a housekeeper or companion. No children. Voted £12.
4. M.D. Aberd., aged 76. No income, and nearly blind. No children; has been suddenly deprived of help from relations. Voted £18.
5. Widow, aged 58, of M.R.C.S., L.S.A. Husband has recently died, and furniture has been sold to meet pressing liabilities, which proceeds of the death vacancy if sold will not cover. Six children, but only able to give very slight help. Voted £12.
6. Widow, aged 60, of L.F.P.S. Glas. Left without provision at husband's death several years ago, and has hitherto supported herself by acting as nurse companion or housekeeper. No children. Voted £12.
7. Daughter, aged 61, of late M.D. Edin. No means. Used to maintain herself as a governess, but for the last few years has been compelled to devote all her time to an invalid sister. Slight help from friends. Relieved three times, £36. Voted £12.
8. Widow, aged 34, of M.B., C.M. Glasg. Income £18 a year. Is acting as nurse at a provincial hospital, but only receives £5 as salary for the first year. Two children, aged 12 and 11, both at an institution, but obliged to be removed before the holidays on account of an outbreak of diphtheria. Relieved three times, £20. Voted £10.
9. Widow, aged 49, of L.S.A. Since husband's death has endeavoured to support herself by giving music lessons and letting rooms, but has been obliged to use a small legacy left by an aunt a few years ago and now exhausted. Two daughters, aged 15 and 14. Relieved twice, £20. Voted £10.
10. Wife, aged 39, of M.R.C.S., L.R.C.P., who is confined in a county asylum. No income; receives £1 a week as a district nurse, but has to pay her rent and other unavoidable expenses. Three children, the youngest only 3. Relieved once, £12. Voted £12.
11. Daughter, aged 49, of late M.R.C.S., L.S.A. Is a trained nurse but has been in bad health for the last few years and for some months past has been quite incapacitated. No income. Relieved once, £5. Voted £10.
12. M.R.C.S., L.S.A., aged 63. For the last few years has endeavoured to support himself by locumtenencies, but has recently been incapacitated by ill health for some months and is now only able to undertake quite light work. Two sons only earning a small weekly wage; wife is endeavouring to establish a boarding house. Relieved once, £10. Voted £10.
13. M.R.C.S., aged 65. For the last two years has been incapacitated by serious heart disease. No income; only very slight help from children; wife receives paying guests. Relieved twice, £30. Voted £18.
14. Widow, aged 64, of M.R.C.S. Eng., L.R.C.P. Edin. Only income £20 a year from a house, the lease of which expires in a few years' time, and to which expensive repairs have been necessary. Relieved nine times, £102. Voted £12.
15. Daughter, aged 64, of late M.D. Lond. Has supported herself for several years by work of different kinds, but finds it increasingly difficult to get. Relieved once, £5. Voted £5.
16. Daughter, aged 62, of late M.D. Edin. Has maintained herself for many years; but now unable to do so on account of defective eyesight. Receives a little help from a fund for poor ladies. Relieved four times, £46. Voted £12.
17. Widow, aged 50, of L.R.C.S. Edin. Quite unprovided for at husband's death. Maintains herself by letting lodgings, with slight help from a son and daughter, but has had her rooms unoccupied for some months during the summer. Relieved three times, £25. Voted £10.

A Urethral Ointment Introducer.

Dr. N. WALMISLEY (London, W.C.) writes: For the last five months I have been using an instrument for applying ointment to inflamed patches of the urethra with much success. I designed the instrument; it consists of a flexible catheter about 4 in. to 5 in. long, with an acorn-shaped tip. There is a hole at the tip only. The catheter, by means of an intermediate piece, is screwed on to a collapsible tube which contains ointment, and the ointment enters the urethra by pressing on the tube. After use the whole catheter is screwed into a firm cover, which keeps it clean and prevents the ointment coming out. I found it useful in the case of patients who could only attend occasionally, the inflamed parts being located by the urethroscope, and the patients only applied the oint-

COMPENSATION FOR INDUSTRIAL DISEASES.

THE recommendation contained in the *Second Report of the Departmental Committee on Compensation for Industrial Diseases*¹—that cataract in glassworkers, telegraphists' cramp, and a wider application of the term "eczema," should be included in the schedule of industrial diseases for which compensation may be claimed—is a most interesting contribution to the subject of diseases of occupation.

GLASSWORKERS' CATARACT.

Glassworkers' cataract has been discussed at meetings of the British Medical Association, and has received very careful consideration in our columns on various occasions. We would mention specially the valuable contributions of Mr. Simeon Snell and Dr. William Robinson. Mr. Snell's investigation led him to the belief that while cataract occurred in glassworkers as in other trades, there was not sufficient evidence, at the time he concluded his inquiries, to warrant the opinion that the disease was unduly prevalent among them. Dr. Robinson, on the other hand, came to the conclusion that the disease was more liable to appear in glassworkers (particularly bottle-finishers) than in the rest of the population. Continental experts, such as Meyhofer, Rohlinger, J. Hirschberg, and E. Cramer, favour the view that cataract in glassworkers is in excess of the normal. Dr. Legge reports that all glassworkers who are exposed to incandescent molten glass suffer, and that changes in the lens are about five times as frequent in glassworkers between 30 and 40, twice as frequent in those between 41 and 50, and over three times as frequent in those over 50, as in other persons.

Of the different grades of glassworkers it is worth noting that "gatherers" in sheet glass are apparently least affected. A "gatherer" is an apprentice, or at any rate a young man; his duty is to dip the pipe into the molten metal to take up the required amount; he looks into the tank each time he "gathers," and his face frequently becomes blistered by the heat. His youth and the fact that he is compelled to shield his face from the intense heat may explain his comparative freedom.

As to the form of the cataract, Dr. Robinson states that it begins as a posterior cortical cataract, and that it differs from the ordinary posterior cortical cataract in that at its commencement it is cobweb-like and saucer-shaped. It is best seen by direct examination with a +10 or +12 lens; the outline is irregular, neither radial nor rosette-shaped. When removed, sight is good, but the workman is rarely able to resume work as a "finisher" on account of loss of accommodation.

In regard to the etiology of the condition, there does not appear to be, as yet, sufficient data to permit the formation of any positive opinion as to whether heat rays or light rays, or both, are to be set down as the cause.

We look forward to an authoritative verdict on this matter from the Committee of the Royal Society, which is considering the question of causation and its corollary, prevention.

A most noteworthy point in the recommendation is that which compels the workman to undergo an operation in order to receive compensation, the wording being that "cataract in glassworkers" be added to the first column of the schedule, and "processes in the manufacture of glass, involving exposure to the glare of molten glass" be added to the second column, and that compensation should be payable only in cases in which an operation is undergone, and for a period not exceeding six months. This compulsion to have an operation is an entirely new departure in the business of compensating the industrial wounded. It is one which will in all probability be extended in the near future. Judicial tribunals have mostly felt themselves unable to take the responsibility of ordering an operation to be carried out, and the experiment of including such a stipulation in an Act of Parliament will be watched with the very greatest attention.

TELEGRAPHISTS' CRAMP.

The addition of telegraphists' cramp to the schedule is a measure of justice to a hard-worked body of public

servants. The symptoms of pain, discomfort at work, and the signs of spasm, tremor and weakness make their appearance just when the officer has reached the stage of perfection in manipulation of the Morse key instrument; it does not develop during the period of learning, when the muscular effort and attention are greatest.

The disorder is to be distinguished from such conditions as local muscular weakness, neuritis, rheumatism, nervous diseases. The most pathognomonic sign is recorded on the Morse signalling slip; this shows jerkiness and illegibility. It appears that about 2.75 per cent. of the total staff employed in telegraphy is affected with the disease, and it is more than doubtful if it is curable. Once it is established, the operator will be compelled to find other employment, for he becomes unreliable and may cause disastrous mistakes in his messages.

In view of the fact that the postal medical officer has the advantage of knowledge of telegraphists' work, he is substituted for the certifying factory surgeon as the person by whom, in the first instance, the disease is to be certified.

Cases which occur in other employments than that of the Postmaster-General are left to the ordinary procedure provided by the Acts.

DERMATITIS FROM IRRITANTS.

The widening of the definition of eczematous ulceration in the schedule is intended to settle the question whether laundry women, who suffer by the irritation produced on their hands and arms by the alkaline solution with which they work, are included in the terms of the definition. There can be no doubt now that these are included, and it is certain that cases will arise due to working with liquids in other employments, it being necessary to establish the fact that the conditions of employment are the exciting cause of the eczematous ulceration. The description of the disease or injury will now read:

Eczematous ulceration of the skin produced by dust or liquids, or ulceration of the mucous membrane of the nose or mouth produced by dust.

By an order dated December 2nd, the Home Secretary has added cataract in glassworkers and telegraphists' cramp to the list of diseases in respect of which compensation is payable.

AUSTRALASIAN MEDICAL CONGRESS.

(Continued from p. 1760.)

WORK IN THE SECTIONS.

Medical Section.

DR. TAIT SUTHERLAND stated that chloroform was specially dangerous in any form of anaemia, and advised that in all such cases requiring a general anaesthetic the ethyl-chloride-ether sequence should be followed. Dr. ZWAR, in a paper on spinal anaesthesia, noted that unpleasant sequelae were far more frequent than was generally supposed to be the case. In a discussion on syphilis which arose in the Medical Section, it was observed that many conditions which were claimed by the pathologists to be syphilitic had not been found to be so. It was clinical evidence that established syphilis as the basis of ascending degeneration of the cord, and not pathological evidence, and the dictum of the pathologists that all arterial degeneration was syphilitic could not be accepted. Dr. J. F. WILKINSON read a very interesting paper on modern methods in the diagnosis of gastric disorders, demonstrating the simplicity with which the general practitioner could ascertain himself the character of the gastric contents, particularly as to the presence or otherwise of free hydrochloric acid. He favoured the dimethylamidoazobenzol, the sodiumlazarinsulphonate, and the phenolphthalein tests. Dr. J. W. SPRINGTHORPE, in a paper on blood pressure in disease, stated that the record given by Martin's haemodynamometer represented simply the amount of pressure required to prevent the brachial pulse wave from reaching the corresponding radial artery. It did not represent the mean systolic pressure, the arterial expansion, or the local condition of blood vessels, or circulation. It was no certain index of cardiac muscularity, arterial elasticity, nervous control, or peripheral resistance. It was simply a numerical record of what the fingers should observe, educationally suggestive, but not conclusive. It had no direct diagnostic value nor was it pure prognostic. People

¹ London: Wyman and Sons; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby, 1908. 73d.

died with a lower blood pressure than normal and live with perhaps one that used to be called dangerous. It did not vary in any definite ratio with temperature pulse, or nervous stimulation. It might vary considerably with meals and show its maximum when a failing heart was fighting against extensive peripheral resistance. It appeared unusually low in pneumonia, typhoid, and influenza, but cases with a blood pressure never above 70 had gone through severe attacks successfully without any special treatment. It had not been found to be of definite value in the selection of an anaesthetic. It ranked thus with the sphygmograph and similar instruments of precise record. Like them it required expert interpretation and experience before basing action upon it. Dr. JULIAN SMITH, in a paper on tuberculo-opsonins, emphasized their value. The general opinion of the section was that vaccine therapy could be quite as efficiently carried out without resorting to such a cumbersome and time-absorbing process as taking the opsonic index was. It was admitted, however, that opsonin work had taught much as to the value of vaccines, and the consensus of opinion was that vaccine treatment with steadily increasing dosage was of immense value in surgical and genito-urinary tuberculosis, but that its position in pulmonary tuberculosis had yet to be ascertained. Sanatorium treatment was shown to be very effective under the climatic conditions of Australia.

Physiology and Pharmacology.

Two meetings of the Subsection of Physiology and Pharmacology were held, and a number of papers of varied interest were read and discussed. Dr. H. G. CHAPMAN (Sydney) gave the results of his investigations on the pharmacology of strychnine, and showed that in animals of the genus *Hyla*, this drug had a curare action as well as the normal action on the cord. A second paper by the same author dealt with the acid reaction of fresh milk. It was due not to lactic acid but to acid phosphates and caseinogen. Dr. KILVINGTON (Melbourne) communicated the results of his recent work on nerve regeneration, and showed how important such considerations were in the surgical treatment of certain paralyses. Miss KINCAID, B.Sc. (Melbourne), gave the results of her analyses, chemical and calorimetric, of the flesh of the rabbit and crayfish. From the standpoint of caloric value and percentage of protein, carbohydrates, and fat, rabbits' flesh had a high nutritive value, but the small amount of extractives present probably prevented this foodstuff from entirely replacing meat. Mr. SYME JOHNSON (Melbourne) found in two samples of 24-hour urine from a case of myasthenia gravis that the kreatinin and phosphate content was abnormally low. Dr. ROTHERA (Melbourne) demonstrated a delicate and reliable test for acetone in urine, which depended on the colour developed on addition of nitro-prusside of sodium, ammonia and ammonium sulphate. Papers of mere technical interest were the existence of a lumen in chemical stimulation, by Dr. MARGARET JAMIESON (Melbourne), and the elasticity of rubber balloons and hollow viscera, by Professor OSBORNE (Melbourne).

Section of Surgery.

At the first meeting of the Section of Surgery a discussion on the surgical diseases of the bile passages and pancreas was opened by Dr. ANSTAY GILES (Adelaide), who dealt chiefly with technique. Dr. CRITCHLEY HINDER (Sydney) followed with remarks on the diagnosis of the different conditions calling for operation, and the cause of some of the symptoms, particularly the pain of so-called biliary colic, which he regarded as due mainly to distension of the gall bladder, or occasionally to adhesive peritonitis. The symptoms of so-called "biliousness" were due, he said, to toxic absorption, partly cholaemic, partly of toxins formed by organisms. The absence of jaundice was of no value in diagnosis. In the discussion Drs. FIASCHI, MATTLAND, BOWKER (all of Sydney), DUNCAN (Kyneton), COOKE, BIRD, MOORE, SYME (all of Melbourne), JACKSON (Brisbane), and RAMSAY (Launceston) spoke; and chiefly differed as to the advisability of performing cholecystectomy.

In the afternoon a combined meeting of the Sections of Surgery and Gynaecology was held to discuss the surgical treatment of septic peritonitis, opened by a paper by Dr.

CHISHOLM (Sydney), and followed by Drs. DUNCAN, HINDER, FIASCHI, BOWKER, MATTLAND, WORRELL, J. A. G. HAMILTON, SYME, MOORE, and THRING. The chief points discussed were the value of flushing the cavity and of saline rectal infusions by Murphy's plan. All agreed as to the necessity of early diagnosis and drainage, but great diversity of opinion existed on all other points.

On the second day a discussion was held on the surgery of non-malignant diseases of the stomach, opened by Dr. W. H. BROWN (Colac), who strongly advocated excision of ulcers rather than gastro-enterostomy, in cases where there was no obstruction, and detailed his method of technique. He also advocated gastro-enterostomy in acute dilatation. He was followed by Dr. FIASCHI, who summarized the results of all his cases, giving a tabulated statement. Dr. RAMSAY discussed the various methods of technique and the cases requiring operation. Dr. BIRD questioned the value of gastro-enterostomy in cases of very greatly dilated stomach. He did not approve of gastro-enterostomy in cases of perforated gastric ulcer. Dr. HINDER still used anterior gastro-enterostomy, and found it satisfactory. He frequently used the Murphy button. He did not approve of operation in acute dilatation of the stomach. He had done gastro-enterostomy in cases of perforated gastric ulcer, with good results. Dr. BOWKER also used the anterior method, and found Harrington's rings a valuable aid. Dr. MATTLAND had formerly done anterior, but now performed the posterior, no-loop gastro-enterostomy, and his results were equally good with each. Excision of ulcers was good in theory, but disappointing in practice. He would operate for acute haemorrhage. Dr. JACKSON referred to the diagnosis of neurasthenic conditions, and found if cases were not improved by rest and simple treatment, they were neurasthenic. He had given up Murphy's button. Dr. MOORE thought it necessary to suture the opening in the mesocolon, and had two cases of intestinal obstruction from small intestine passing through the opening. Dr. SYME discussed the treatment of hour-glass stomach. In greatly-thickened ulceration he had seen haemorrhage a considerable time after gastro-enterostomy, and advocated a partial gastrectomy for such cases. He had operated for acute haemorrhage, but it was exceptional to do so.

On Thursday afternoon Dr. MATTLAND read a paper on the use of the cystoscope in obscure renal disease; illustrated by cases. Dr. DUXHILL gave his experiences in the surgical treatment of exophthalmic goitre, based on 47 thyroidectomies for this condition. He is an enthusiastic advocate of the operation, and objects to crushing the gland, which, he says, can be cut with impunity. Dr. HINRICKSEN read a paper on Bier's hyperaemia in acute inflammation, which he had found very satisfactory. At the last meeting a discussion on the surgery of nerves and paralysis was opened by Dr. BASIL KILVINGTON, who very modestly related the results of his original investigations, and discussed the cases of infantile paralysis most suitable for treatment by operation on nerves, and those most suitable for tendon transplanting. Dr. H. S. NEWLAND followed on much the same lines, giving, however, greater credit to Dr. Kilvington's work. Dr. DUNCAN contributed a paper on the treatment of facial neuralgia, especially with reference to the removal of the Gasserian ganglion; and Dr. O'HARA demonstrated a new method of approaching and removing the Gasserian ganglion. Dr. E. S. JACKSON read a paper on the association between dental caries and appendicitis, maintaining that dental caries favoured the occurrence of appendicitis, and appealing for more care in preventing teeth troubles. Mr. R. HAMILTON RUSSELL exhibited a series of surgical cases possessing unique interest at the Alfred Hospital. Among these were two cases of bone implantation. In the first case, a severe compound fracture of the skull, a portion of the frontal bone was replaced nine days after its removal; in the second case a portion of the ulna affected with myeloid tumour had been removed, and a portion of an ulna removed from a corpse substituted. In both cases the result attained was perfect. He also showed the result of an operation devised for deformities of the arm resulting from removal of a portion of the radius some years previously; and a series of cases of tuberculosis of the knee-joint operated upon by his method of anterior longitudinal incision through the patella.

Diseases of Children.

A Section for Diseases of Children was included in the programme of the session held in Melbourne eighteen years ago, but the attendance of members was so small that the section was omitted from all subsequent sessions until the present one. On this occasion it proved to be one of the most attractive sections in the Congress. The members of the honorary medical and surgical staff gave demonstrations each morning and exhibited a large number of cases. The President was Dr. A. JEFFERIS TURNER (Brisbane), and the Secretary Dr. A. JEFFREYS WOOD. The first morning was devoted chiefly to the exhibition of cases of congenital and acquired syphilis in children, and the proneness to the ravages of tubercle in congenital syphilitis was well illustrated. A number of cases of obstetrical brachial palsy were also shown, and the good results following operative treatment were shown by several cases. An interesting group of 4 cases from one family suffering from this form of paralysis was also shown. Clinical demonstrations were given on cases of syringomyelia, pseudo-hypertrophic paralysis, congenital malformity of the heart, chorea, and bronchopneumonia. Papers were read on congenital syphilis by Drs. ATKINSON WOOD and P. B. BENNIE, and a discussion followed. A most instructive paper on lead poisoning in childhood was read by the President, Dr. JEFFERIS TURNER of Brisbane. After lunch the Section met in conjunction with the Section for Neurology and Psychiatry at the Children's Hospital, and a large number of cases of mental deficiency in childhood were shown. Children with spastic paraplegia the result of meningeal hæmorrhage and of encephalitis were demonstrated. A large number of Mongolian imbeciles were included amongst the cases, and one little girl of 8 months with the characteristic signs of this form of imbecility was shown side by side with her twin brother, who was absolutely normal in every way. The sporadic cretins formed a very interesting group, as they included some cases that had been under treatment as long as ten years, and were still taking thyroid. The best of these was a girl of 12 years old, who was in the fourth class of a State school, and was beginning to show signs of commencing puberty. No one talking to this child would have imagined that she had been a marked case of sporadic cretinism unable to walk at the age of 4 years, when she first came under treatment. Dr. A. W. CAMPBELL of Sydney concluded the demonstration with a masterly and instructive lantern demonstration of the brain in amentia.

On Wednesday, October 21st, Dr. W. KENT HUGHES commenced the demonstration by reducing a case of congenital dislocation of the hip. Numerous cases of successful reductions of these hips were on exhibition, and the skiagrams shown left no room for doubt as to the perfect results obtained by the bloodless reductions. A lantern demonstration by Dr. HUGHES on the anatomy and treatment of talipes equino-varus, and another by Dr. H. M. HEWLETT of some interesting medical and surgical cases, were much appreciated by members. Dr. A. JEFFREYS WOOD read a paper on the treatment of congenital dislocation of the hip.

On Thursday morning, October 22nd, a large number of cases of spinal caries and morbus coxae were shown by the members of the honorary medical staff. Some of the older cases shown illustrated the subsequent shortening of the whole limb that frequently results from tuberculous disease of the hip-joint. Lovett's method of forcible correction in scoliosis was demonstrated by Dr. H. DOUGLAS STEPHENS, and the plaster-of-Paris jacket applied to a patient with marked rotation. Dr. P. B. BENNIE gave a most instructive demonstration of the method he adopts in measuring a patient for a single Thomas's hip splint. A discussion on the treatment of tuberculous disease of the hip-joint was opened by Dr. CLUNIE (Sydney), who said that the treatment of this affection by Thomas's splint was confined to the Children's Hospital, Melbourne. All the members who had watched the results following the treatment of hip cases by well-fitting Thomas's splints were emphatic in declaring that as a method it was simpler and more effective than any other kind of treatment, and was especially useful in allowing the patient to be carried out into the open air. A discussion on the prevention of the introduction of infectious diseases

into children's hospitals was opened by papers from Drs. W. E. SCIMMONS and R. D. McMASTER (Sydney).

Friday, October 23rd, was the last day on which the Section met, and numerous cases of infantile paralysis were shown by members of the staff. An epidemic of this disease commenced in April, 1908, and an account of it was given by Dr. H. DOUGLAS STEPHENS. The disease, he said, had been endemic in Victoria, especially in some of the suburbs of Melbourne, for some time, certainly during the last decade, and notably amongst the more densely populated portions of the metropolitan area. During the recent epidemic no relationship could be traced between it and the undue prevalence or absence of other diseases, nor was there any similar affection noticeable amongst animals. Sanitary conditions were good as a rule, but overcrowding in small houses was a common feature. The outbreak occurred in the autumn, after an exceptionally dry, warm summer—a dearth of water in the catchment area—such as had not been experienced for many years. In his opinion the disease was mildly contagious. The incubation period would seem to be somewhere between three and sixteen days, and the average duration of the invasive or preparalytic stage something under seven days, commonly twenty-four to seventy-two hours. Lumbar puncture was performed in 26 early cases and the fluid examined by the bacteriological department of the Melbourne University. In 7 cases a coccus not unlike in many features the diplococcus isolated by Geiswold in the Norwegian epidemics was demonstrated, but up to the present time its causal relationship had not been proven. *Post-mortem* examinations were made in several cases, and, although showing very little macroscopically, demonstrated clearly under the microscope the widespread inflammatory lesions described by Harbitz and Scheele. The extreme rapidity with which the anterior cornual cells disappeared was a remarkable feature. Although the great majority of cases exhibited the usual paralysis characteristic of poliomyelitis of the strictly spinal type, the epidemic produced other variations of the disease, aptly described by Batten under the terms polio-encephalitis, superior and inferior, including variations suggestive of acute cerebellar ataxia and Landry's paralysis. Of the preparalytic manifestations the commonest were fever, vomiting, irritability, restlessness, delirium, twitching, pain—sometimes severe and widespread, and occasional rigidity of spine and neck. Constipation, often very obstinate, and retention of urine of transient nature were very frequently noted. The epidemic included over 130 cases, and gave a mortality-rate of approximately 4.5 per cent. Dr. W. C. MACKENZIE read a paper on the treatment of infantile paralysis, and laid special emphasis on the usefulness of early splinting of the affected limbs with a view to prevent the overstretching of the affected muscles. Dr. R. B. WADE (Sydney) also sent a paper, which was read by the SECRETARY, dealing with a similar epidemic that occurred in New South Wales in 1903-4, and also with the treatment. The numerous forms of splints and apparatus used in helping the children to walk were exhibited. Thomas's caliper knee splint, Crabbe's splints, and the various braces all excited the keen interest of members. A few cases of tendon transplantation were shown.

UNDER the will of the late Miss Isabella Gregson, of Bournemouth, a sum of £5,000 is directed to be paid to the Children's Infirmary, Myrtle Street, Liverpool, for the endowment of five beds.

THE position of Livingstone College, as shown by the report published on December 8th, seems more satisfactory than at any time since the institution was founded some fifteen years ago. The number of new entrances during the year 1907-8 was much larger than any hitherto recorded, being an average of 30 in each of the three terms. Rather more than half the students entered for the full session and others for one or two terms. The details given as to the students show that the college remains as heretofore thoroughly undenominational. The financial statement shows that a deficiency of over £400 existing at the beginning of the year has now been wiped out, and that the working expenses of the year were practically met by the fees of the students. Nevertheless, there still remains a mortgage on the property amounting to some £3,500. Particulars of the training in medical matters afforded to missionaries can be obtained on application to Dr. C. F. Harford, Livingstone College, Leyton.

THE COMPOSITION OF CERTAIN SECRET REMEDIES.*

XXII.—MEDICINES FOR GENERAL USE.

By far the greater number of the proprietary medicines which have been described in this series of articles are recommended for a wide range of ailments, but usually there is some one disease for the treatment of which they are particularly recommended, so that it has been possible to classify them according to their alleged purposes. In very many other cases, however, the claims made are so wide that the article is put forward as a sort of cure-all. A selection of such preparations is here dealt with; they are not sharply marked off from more special preparations, for many of them are recommended for some one disease, of which nearly all others are asserted to be variations.

DR. MARTIN'S MIRACLETTS.

Supplied by Dr. Martin's Medicine Co., 6, Pantion Street, Haymarket, London, S.W.

Price 1s. 1½d., 2s. 9d., 4s. 6d., and 11s. per bottle. A 2s. 9d. bottle contained sixty tablets.

These are described on the package as:

A real Elixir of Life in solid form. The world's greatest remedy.

Cures Constipation, Indigestion, Headache, Neuralgia, Anæmia, Nervous Disorders, Liver Troubles, Rheumatism, Sciatica, Gout, St. Vitus's Dance, Hysteria, Rickets, Heart Disease, Kidney Complaints.

Cures Melancholia, Loss of Appetite, Sleeplessness, Lassitude, Mental Depression, Brain Fag, Palpitation, Stomach Disorders, Women's Special Ailments and Irregularity of Health, etc., etc.

A little booklet entitled "A Fortune for All" was enclosed in the package; the following are extracts from this:

Dr. Martin has been studying this question of Perfect Health for the last nine years, and after continuous experiments which have cost a small fortune, he has succeeded in discovering a remedy which he claims to be the most WONDERFUL in the WORLD. Having found the remedy Dr. MARTIN has for the last six months given away a large quantity to various people in all conditions of life, with the result that the most astounding and marvellous cures have been effected.

Dr. Martin's Miracletts are a REAL ELIXIR OF LIFE in solid form. They arrest decay of nature, act upon the blood and tissues of the body, giving one a continually youthful appearance, with every attribute of health, strength, and beauty.

Whatever you may be suffering from do not worry or fear, as Dr. MARTIN'S MIRACLETTS will be certain to cure you!

Dr. Martin's Miracletts make the weak and sickly become strong and healthy, and the aged become youthful and full of energy; the tired worn out look being replaced by an appearance of cheerfulness and vivid health. The pale and wrinkled face with bad complexion gives way to rosy cheeks and a clear skin; the thin gain flesh, and the stout lose superfluous fat; indigestion quickly disappears, the appetite returns, and a new life is open to all.

A separate small slip enclosed in the package is worded as follows:

GUARANTEE.

Dr. Martin's Medicine Company being absolutely confident of the marvellous curative properties of their Miracletts, will willingly refund the money to any purchaser who has taken eighteen Miracletts according to directions, and is not satisfied with the results.

Much less conspicuously, on another slip chiefly devoted to the relative quantities in the packages of different size, it is stated:

Those whose ailments have been of long standing must not expect immediate perceptible results, but with a little patience and perseverance the result is SURE.

The directions are:

For Adults.—In ordinary cases one Miraclett should be taken after each meal three times a day. For obstinate and extreme cases of constipation two Miracletts may be required three times a day.

For Children.—For children over ten years one Miraclett only should be taken after the last meal at night.

The "Miracletts" consisted of sugar-coated tablets, the coating being coloured brown with ferric oxide (so-called chocolate coating). After removal of the coating they had

an average weight of 4.3 grains; this includes the weight of a strong coating of varnish, which was not removed with the sugar coating. Analysis showed them to contain valerianates of quinine and zinc, ferric oxide, menthol, kaolin in considerable quantity, and a little talc. A substance of extract nature was also present to the extent of about 5 per cent.; it possessed no characteristic taste or other property by which it could be identified; a resinous substance which was found in small quantity appeared to be merely the varnish with which the tablets were covered. The quantities of the different ingredients were determined as nearly as possible, and the results indicated the following amounts:

Quinine valerianate	0.4 grain
Zinc valerianate	0.1 "
Ferric oxide	0.3 "
Menthol	0.03 "
Kaolin and talc	2.3 grains

In one tablet.

Estimated cost of ingredients of tablets, 4d. per hundred.

THERAPION No. 3.

Prepared by the Le Clerc Medicine Company, London, England.

Price 2s. 9d. per package, containing 1½ oz.

The following is a sample of the advertisements of this preparation:

A Broken Down System.

This is a condition (or disease) to which doctors give many names, but which few of them really understand. It is simply weakness—a breakdown as it were of the vital forces that sustain the system. No matter what may be its causes (for they are almost numberless) its symptoms are much the same, the more prominent being sleeplessness, sense of prostration or weariness, depression of spirits, and want of energy for all the ordinary affairs of life. Now what alone is absolutely essential in all such cases is increased vitality—vigour—

Vital Strength and Energy,

to throw off these morbid feelings, and as night succeeds the day this may be more certainly secured by a course of

The New French Remedy,

Therapion No. 3.

than by any other known combination. So surely as it is taken in accordance with the directions will the shattered health be restored,

The Expiring Lamp of Life Lighted Up Afresh,

and a new existence imparted in place of what had so lately seemed worn, "used up," and valueless. This wonderful medicine is suitable for all ages, constitutions, and conditions, in either sex, and it is difficult to imagine a case of disease or derangement, whose main features are those of debility, that will not be speedily and permanently benefited by this never-failing recuperative essence, which is destined to cast into oblivion everything that had preceded it, for this widespread and numerous class of human ailments.

In a pamphlet which is enclosed in the package similar statements to the above are made, together with others which indicate that the medicine is primarily intended for loss of sexual power, and followed by a dissertation on "Venereal Excesses and their Consequences." "Therapion No. 1" and "Therapion No. 2" are also described, the former as

the most efficacious remedy ever discovered for the removal of all discharges in either sex,

and the latter as

the great remedy for impurity of the blood, scurv, pimples, spots, blotches, pains and swellings of the joints, gout, rheumatism, syphilis, etc.

The directions are:

For either No. of Therapion a piece about the size of a small marble, as indicated herewith, should be taken three or four times a day—an hour or less after meals.

The contents of the 2s. 9d. package are referred to as twenty ordinary adult doses; at this rate one dose would be 30 grains. The substance consisted of a dark stiff paste smelling strongly of camphor. Analysis showed it to contain, in addition to camphor, glycerine, powdered liquorice, a bitter extract agreeing in all respects with extract of gentian, calcium glycerophosphate, and a trace of alkaloid; there also appeared to be a second extract present. The alkaloid, which amounted to 0.06 per cent. only, could not be identified with any of the ordinary medicinal alkaloids. There was some evidence that the second extract was that of damiana, and a paste made up

* Previous articles of this series were published in the following issues of the BRITISH MEDICAL JOURNAL:—1904, vol. ii, p. 1532; 1905, vol. ii, pp. 27, 1645; 1907, vol. i, p. 215; vol. ii, pp. 24, 160, 209, 335, 530, 653; 1908, vol. i, pp. 833, 912, 1373; vol. ii, pp. 86, 505, 1022, 1110, 1193, 1285, 1566, 1697, 1875.

with this and the other ingredients agreed well with the original; but extract of damiana possesses no distinctive characters by which it can be identified in a mixture. Quantitative determinations were made of those ingredients capable of it, and the proportions of the others estimated by comparison. The results indicated the following formula:

Camphor	2.5 parts
Glycerine	24 "
Powdered liquorice	40 "
Calcium glycerophosphate	1.8 "
Extract of gentian	5.0 "
Extract of damiana (?)	1.0 "
Alkaloid	0.06 "
Water to	100 "

In addition, there appeared to be present a slight trace of the oil of one of the umbelliferous fruits, probably anise or fennel. Disregarding the trace of alkaloid, the estimated cost of ingredients for $1\frac{1}{2}$ oz. is 2d.

DR. WILLIAMS' PINK PILLS FOR PALE PEOPLE.

Sold by the Dr. Williams Medicine Company, 46, Holborn Viaduct, London, E.C. Manufactured in the United States of America. Price 2s. 9d. per box, containing 30 pills.

These pills are advertised for a great variety of diseases, prominence being usually given to one disease in each advertisement; thus four long advertisements appearing simultaneously in different papers are respectively headed:

Afraid of being touched. So sore with Rheumatism. A once-crippled victim tells how Dr. Williams' Pink Pills cleared his system of Rheumatism.

Eczema expelled. Mr. John Chamberlain tells how his sufferings from Skin Disease were cured by Dr. Williams' Pink Pills.

Sciatica's Swift Pains rendered this Lady helpless. Her case had defied treatment, but Dr. Williams' Pink Pills succeeded by curing the cause of Sciatica.

The Dark Days of Dyspepsia. . . . Dr. Williams' Pink Pills go to the very cause of the mischief.

Each includes a long description of a "case," usually with a picture. The following is from the concluding paragraph of the first of these advertisements, and the others end in a similar way:

THE DR. WILLIAMS' WAY.

When the muscles and nerves are tortured by poisons in the Blood, be the result Rheumatism, Sciatica, or Lumbago, the only way to a cure is to Enrich and Purify the Blood. Dr. Williams' Pink Pills, in this way alone, have cured not only Rheumatism, but Anaemia, Indigestion, Palpitations, Influenza's After-Effects, Eczema, Sciatica, St. Vitus' Dance, Spinal Weakness, the many forms of Nervous Disorders dreaded by men; also the special ailments of women.

In a circular enclosed in the package it is stated that

The success of this remedy lies in the recognition of the controlling influence of the blood over the health of the body. It is the root of disease that must be attacked, and the most important development of modern medical science has been in discovering that, in most diseases, this lies in the condition of the blood. If the blood is thin and poor, the nerves cannot receive their proper nourishment, the system becomes run-down, and in a condition to invite disease. Build up the blood, restore the worn-out nerves and you remove the cause. Dr. Williams' Pink Pills for Pale People contain elements necessary to give new life and richness to the blood.

General Directions.—Before beginning to take these Pills, *ease the bowels as they may be opened by laxative or purgative medicines.* It is best to begin with one of Dr. Williams' Pink Pills after each meal, commencing the use of the medicine after a mid-day meal. Being stimulating, it is best not to take them on an empty stomach. After taking for a few days the number may be increased to two Pills at a dose, while in severe cases three may be taken at a time.

The pills were ovoid in shape and coated with sugar, coloured pink; after removal of the coating they had an average weight of 3 grains. Analysis showed them to contain ferrous sulphate, potassium carbonate (these two having reacted more or less completely, and about one-third of the iron having become oxidized to the ferric state), magnesia, powdered liquorice, and sugar. Since it has been stated that these pills contain arsenic, careful search was made for it, but it was not found. The pill is thus merely one of the many variations of Bland's pill. The quantities of the different ingredients found indicated the following formula:

Exsiccated sulphate of iron	...	0.75 grain
Potassium carbonate, anhydrous	...	0.66 "
Magnesia	...	0.09 "
Powdered liquorice	...	1.4 "
Sugar	...	0.2 "

In one pill.

Estimated cost of ingredients for 30 pills, one-tenth of a penny.

BEECHAM'S PILLS.

Prepared by Thos. Beecham, St. Helens, Lancs.

Price 1s. 1½d. per box, containing 56 pills.

These pills are very widely advertised in a variety of ways. The following is a specimen of the statements made:

Ordinary medicines begin at the wrong end, only correct symptoms. People take headache powders for headaches, blood medicines for the blood, and nerve remedies for nervousness, when they only need Beecham's Pills to tone up the digestive organs, the liver and the kidneys, and so keep the whole system in a healthy condition.

In a circular wrapped round the box it is stated that:

These renowned pills are composed entirely of MEDICINAL HERBS, and are warranted free from mercury or other poisonous substance. . . . Persons of a strong or average constitution, but who may temporarily be suffering from any of the complaints herein mentioned, will usually find the dose to suit them to be three or four pills once a day: sometimes, however, it is necessary to repeat this dose morning and night, according to the condition of the system at the time. No harm can be done by increasing the dose where it is found insufficient, as the Pills can never act injuriously. Others, who may be frequently subject to one or more of the specified ailments, should take smaller doses of the pills occasionally, one, two, or three generally being the ordinary dose, which may be increased at discretion by the patient.

The "complaints herein mentioned" include Constipation, Headache, Dizziness or Swimming in the Head, Wind, Pain, and Spasms at the Stomach, Pains in the Back, Restlessness, Insomnia, Indigestion, Want of Appetite, Fussiness after Meals, Vomiting, Sickness of the Stomach, Bilious or Liver Complaints, Sick Headaches, Cold Chills, Flushings of Heat, Lowness of Spirits, and all Nervous Affections, Scurvy and Scorbutic Affections, Pimples and Blotches on the Skin, Bad Legs, Ulcers, Wounds, Maladies of Indiscretion, Kidney and Urinary Disorders, and Menstrual Derangements.

The pills had an average weight of 1½ grains. Analysis showed them to consist of aloes, ginger, and soap; no other medicinal ingredient was found. The quantities were approximately as follows:

Aloes	0.5 grain
Powdered ginger	0.65 "
Powdered soap	0.18 "

In one pill.

Estimated cost of ingredients for 56 pills, one-eighth of a penny.

COLEMAN'S NERVELETES.

Proprietors, J. Chapman and Co., Limited, Norwich.

Price 1s. 1½d. per bottle, containing 27 pills.

A circular enclosed in the package is headed:

Coleman's Nerveletes or Nerve Pills generate brain and nerve-force.

A further extract is as follows:

The busy brainy man has nothing to guide him as to his power of endurance; he works at high pressure, regardless of consequences, until overwork and anxiety produce the inevitable—nervous exhaustion. A little rest and he recovers, rushes head-long again into hard work, increasing the pressure until suddenly one of the small blood vessels on the brain bursts—what is commonly called a stroke—result, Paralysis. How often do we observe commercial and literary men of brilliant attainments gradually become impotent, through the fearful reckless waste incurred by overwork? If we use up more energy and force than we can naturally supply, we require something to assist nature. The man or woman who suffers from Brain Fog, Nervous Debility, Want of Stamina, Physical Weakness, Nervous Dependancy, Sleeplessness, has in Coleman's Nerveletes a most powerful restorative and Nerve Tonic which will prevent wear and tear of nerves, will invigorate the brain, build, brace and buoy you up, enable you to safely tide over great tests of endurance, and if you should unhappily be half or almost completely worn out, quickly restore you so that you can naturally sleep well, eat well, think well, and work well.

Dose: Two Nerveletes daily after dinner.

The pills were coated with talc; after removal of the coating they had an average weight of about 1½ grains. Analysis showed them to contain fer phosphorus, quinine sulphate, a little powdered liquorice, and about 20 per cent. of a powdered vegetable tissue, which could not be identified: the remainder of the pill appeared to be of the nature of excipient only. The amounts of phosphorus and

quinine were determined, and indicated the following formula:

Phosphorus	0.005 grain
Quinine sulphate	0.07 "
Vegetable powder	0.3 "
In one pill.	

MOTHER SEIGEL'S CURATIVE SYRUP.

Proprietors, A. J. White, Ltd., New York and London.
Price 2s. 6d. per bottle, containing 3 fluid ounces.

Although this is described on the wrapper as "for dyspepsia" so many disorders are stated to be due to this cause, and amenable to treatment with this preparation, that it may fairly be included here. On the other side of the wrapper it is called "A cure for impurities of the blood," and "A cure for dyspepsia and liver complaints." In a circular enclosed with the bottle it is stated—

The symptoms mentioned above are the smoke of the fire of indigestion—a fire that will eat out your very vitals and sap your strength and vitality. For it can't be too often repeated that indigestion is the root of a great deal of evil: the origin of a great many disorders which no man quite understands how it came by. And why this is can easily be explained. Disease is poison; its symptoms are the manifestation of the poison. Indigestion creates many dangerous poisons, and is therefore the cause of many diseases.

So let us get rid of the smoke by putting out the fire, and purify our blood and system with Mother Seigel's Syrup, which will sweep away the poisons and make us healthy and strong.

Mother Seigel's Syrup is a highly concentrated, purely vegetable compound, having a specific action on the stomach, liver, and kidneys.

The directions on the label are:

Shake the bottle so as to mix the sediment. Commence by taking ten or fifteen drops three times a day, in a little water. If this does not give relief, the dose may be increased to thirty drops.

Analysis showed the presence of free hydrochloric acid, tincture of capsicum, a bitter substance agreeing in its properties with aloes, and sugar (partly as invert sugar); the colouring and flavouring substances also present indicated that the sugar had been added in the form of treacle. Quantitative determination of those ingredients capable of it, and estimation of the others by comparison with known mixtures, indicated the following formula:

Dilute hydrochloric acid B.P.	10 parts by measure
Tincture of capsicum	17 " "
Aloes	2 parts
Treacle	60 "
Water to	100 parts by measure

Estimated cost of ingredients for three fluid ounces, one-third of a penny.

MOTOR CARS FOR MEDICAL MEN.

(From a Correspondent.)

THE COST OF MOTORING.

IN the course of the past eighteen months we have published a considerable number of communications in which correspondents have given figures as to the cost incurred in using motors for the purposes of medical practice. We have recently received some further communications, and it may, therefore, be useful to analyse the data available to hand with a view of arriving at some sort of average. The material is the more useful in that all shades of opinion are represented, from those who are enthusiastic in praise of the services of their motors to those who are thoroughly dissatisfied, and to the data presented by these particular attention has been given in order to discern if possible the reason for their poor results.

The analysis of the figures and the comparison with the expense of keeping horses, where this is given, is not easy to make, as the various correspondents have included different sets of items, so that the figures have to be dissected out, in order to bring them into comparison; and it has seemed best for the present purpose to separate out what may be called running costs—namely, petrol, oil, tyres, and repairs—and to deal with them by themselves, leaving out of consideration for the moment the cost of a driver and cleaner, garage accommodation, insurance, and especially depreciation. With regard to the item of depreciation there is a good deal to be said, and the subject will be dealt with separately; but it may be at once stated that if the owner will take the trouble to master the mechanism of his car—and it will immensely add to the interest of using it if he does—there

is no need to employ a chauffeur at high wages. It is quite true that a trained mechanic can do more in the way of minor repairs than an ordinary driver, but in the absence of a fully-equipped workshop he cannot by any means do all repairs, and now that repair shops with fairly competent repairers exist in abundance almost everywhere, it is far cheaper to send the car to them when necessary than to pay large wages every week. It is not difficult to teach any intelligent man how to do most of the current adjustments. The writer has two cars, and yet during the five years that he has had two, has never had a "chauffeur," but has taught his coachman to drive, and has also educated him into being a fair mechanic. There is, therefore, really no occasion to pay more than £52 to £64 a year for a driver who will keep the car. If the practitioner is so driven with work that he can never devote half an hour to his car, it may possibly be worth his while to pay more and get a more skilled mechanic, but then presumably his income will be proportionately larger, and the added expense will not matter much. Garage most people possess in the form of a coach house, and with the modern types of motors the great majority of adjustments can be made from above, so that a motor pit is rarely required.

Insurance.

The item of insurance may seem heavy; reasonable protection against all risks may be obtained for a small car for from £9 to £12 a year, but it may be remarked that this carries an insurance against certain risks which one has been in the habit of bearing uninsured with horse-drawn vehicles, such as damage to third persons, cyclists, pedestrians, etc. Still, in the present state of public feeling, when, if an accident occurs, the blame is almost always, whether rightly or wrongly, put upon the motorist, it is desirable to be fully insured.

This brings the total expense up to from £61 to £76 a year, the greater part of which would be incurred even with a single horse.

Depreciation.

Next comes the question of depreciation. There is an immediate and heavy drop in price the moment a car becomes "second-hand," and this drop is out of all proportion to any actual deterioration. Hence if we are to write down as depreciation the full extent of the drop in selling value it becomes a very serious item in the expenditure. Moreover, if a car is to be sold second-hand to the best advantage, it should be sold within a year and a half, and those rich motorists who are not satisfied unless they have the very latest of everything rarely keep their cars more than a year.

But, if the car is kept as a money earner, this frequent buying and selling is not to be thought of, for as a worker the car, if a good one, will not have depreciated in a couple of years, though its selling value would have dropped heavily. To give a concrete example, the writer has one car which cost £550 five years ago, and if sold now would very likely not fetch £120. But it has been completely overhauled, and in almost every particular is as good as new. It has cost in the five years £24 in repairs, many of these being replacements of parts when it was overhauled, parts which would have gone on for years to come, but which the owner as a counsel of perfection thought it better to replace when it was dismantled. Although cars have gone down a little in price, it could not be replaced by a similar new one for less than £450 or £500, and it would therefore be folly to sell it so long as the owner has use for it, as it has in all probability many years of useful life before it. What, then, should be set down as its depreciation? Evidently, so long as it remains a good servant, not the difference between its price when new and what it would now fetch. There are plenty of small cars still in excellent condition which have run their 15,000 miles, while the de Dion Company claim that some of their small cars have run 100,000 miles, and are still useful. Hence it would appear that the most economical way to use a car is to buy a good one, and then work it to the death—that is to say, until its bill for repairs becomes excessive.

Taking these points into consideration it will be seen that the amount to be set down as depreciation becomes a fancy estimate, about which no two people will agree, and so it is better to leave it out, always remembering that it does exist. If it is desired to give a liberal estimate, it

may be put probably at about 10 per cent. of the value of the car while retained and used by the owner. If the car is to be sold again it will be much more.

Actual Running Cost.

An analysis of the actual running costs furnished by our correspondents gives an average cost of nearly 3d. a mile, but this average is vitiated by including some which were as high as 7d. a mile, or even a little more; these will have to be referred to later, as such high costs are susceptible of explanation and are not to be regarded as fair averages.

That an estimate of 3d. a mile should be more than ample is curiously confirmed by a statement in the *Autocar* for December 19th, that a responsible motor agency has contracted with a medical man to garage, wash, adjust and repair, furnish petrol and tyres, completely overhaul once a year, and insure against fire, accident, third party risks and theft, for an inclusive charge of 3d. a mile indicated on the milometer, the car being a 6-h.p. de Dion. The average mileage has been 8,000, so that the owner will have to pay about £100, while, be it remembered, the agency has named a price at which no doubt it expects to make a profit. He, of course, provides his own driver, if he does not drive it himself.

Something under 3d. a mile—indeed, not more than 2d.—is what a small car should cost for what we have included in the running expenses, though few can hope to make it as low as 1d. a mile, the figure given by one correspondent, who uses solid tyres.

A closer examination of the higher figures given at once brings to light as the most salient fact that the repairs and replacements have been altogether excessive. Thus we read of big ends having to be adjusted after a too short mileage, of broken parts, damaged parts, renewals, and all sorts of repairs which in the aggregate ought not to have occurred if the car was a good one to begin with and was well treated.

By a really good car is meant one well designed, well constructed, of good material, of different materials appropriate to its several parts, and well tested before delivery, till—to borrow an expression from Rudyard Kipling—the machinery had "found itself." To the experienced motorist, the record of repeated repairs and replacements for certain cars which proved themselves very expensive plainly spells either an indifferent car or bad treatment. As confirmatory of this, in one case at all events the petrol consumption was about double what it should have been for the mileage. This tells us almost with certainty that for the largest part of the time the engine must have been running very badly.

Of course it is not meant to be implied that even on the best of cars, by bad luck, something may not go wrong early; thus, on the writer's car, which has such an excellent record as to repairs, one of the cones of the ball-bearing of a driving wheel wore badly, and had to be renewed within a few months; but the new one and all the others are still there and practically unworn. It is the occurrence of one thing after another that condemns either the car or its treatment, and the result cannot be taken as an average to be expected and accepted as in the day's work.

To summarize what has been arrived at by a study of the material before us, we may give the following estimate for an 8-h.p. car, two-seated, and of good make:

Running costs at 2d. per mile for 5,000 miles	£ s.
Man and insurance	41 14
	70 0
	111 14

This works out at about 5d. a mile run; as the man and insurance, which have been put not at the lowest but at the medium figure, are fixed charges, a larger mileage would work out at less cost per mile, and similarly with a smaller mileage the figures would be less favourable. These would be out-of-pocket expenses, and if to them we add £20 per annum depreciation on a £200 car we shall get a total cost of about 6d. a mile for 5,000 miles.

This estimate is intended to cover a series of years. In the first year repairs should be negligible, much less than in the estimate, and they should not rise to its level until several years have passed. Further, in forming the estimate in order that it should not be misleading, the allowance for expenses has been somewhat liberal.

In order to secure economy there are certain things to

be observed. A really good car should be purchased, and that car should be kept contentedly for many years. It is essential not to purchase a car of higher horse power than the nature of the country and the work requires, for with increased horse power expenses of all sorts rise rapidly, and the carrying of extra weight, such as a four-seated body or extra passengers, is not to be done for nothing.

If the owner drives himself for the most part and gives a little attention to the car, he can probably secure the services of a suitable man for less than the £60 which is the amount in the estimate, and so reduce his mileage costs. It may be pointed out also that the man's wages alone (in the estimate) amount to nearly 3d. a mile, an amount equally incurred with horseflesh, so that really in instituting any comparison the question must be put whether the cost of horses and carriages can be as little as 2d. to 3d. per mile covered.

COST OF SMALL CAR.

DR. S. T. CROPPER (Chepstow), whose letter has been accidentally delayed, writes to speak well of his experience of an Adams car, 10-12 h.p. He finds it quite easy to manage in traffic and capable of taking the steepest hills in his neighbourhood. His car has run for 5,000 miles, and he finds that it does at least 30 miles to the gallon, and that the total cost per mile, including tyres and petrol, works out at between 2d. and 3d., varying according to the cost of a man to look after the machine.

THE PLAGUE.

PREVALENCE OF THE DISEASE.

INDIA.

DURING the weeks ended October 24th and 31st and November 7th and 14th the deaths from plague in India numbered 2,046, 2,140, 1,993, and 1,943. The principal returns were: Bombay Presidency, 1,174, 1,143, 1,008, and 881; Bengal, 24, 52, 73, and 94; United Provinces, 12, 9, 17, and 22; Punjab, 110, 295, 304, and 322; Central Provinces, 263, 256, 178, and 142; Rajputana, 8, 25, 82, and 122; Hyderabad State, 171, 32, 44, and 26; Central India, 56, 73, 80, and 83; Mysore State, 173, 186, 171, and 164; Burma, 41, 27, 23, and 22.

MAURITIUS.

During the weeks ended November 12th, 19th, 26th and December 3rd and 10th the fresh cases of plague in Mauritius numbered 18, 18, 12, 4, and 7; the deaths from the disease amounted to 11, 15, 7, 1, and 5.

AUSTRIA.

At Trieste, 2 cases of plague reported on September 18th, 1 of which proved fatal.

TURKEY.

At Adalia, September 5th to 23rd, 2 cases of plague reported; at Bagdad, in September, 1 case, 1 death; at Beirut, 1 case on September 23rd.

EGYPT.

From September 4th to October 9th, 23 fresh cases of plague, and 15 deaths from the disease.

BRITISH EAST AFRICA.

At Kisumu cases of plague were reported late in August.

GERMAN EAST AFRICA.

At Muansa on August 19th one death from plague on board a steamer in the port.

CHINA.

At Tongshan, near Tientsin, in the first week of September a serious outbreak of plague occurred. At Wuchang an outbreak of the disease occurred during the first week of September.

JAPAN.

At Hiogo-Ken, between August 15th and September 14th, 35 fresh cases of plague were reported with 22 deaths from the disease. In Japan from January 1st to September 14th the cases of plague were returned as 645 and the deaths from the disease as 574.

SOUTH AMERICA.

Venezuela.—From August 10th to September 6th 7 fresh cases of plague were reported from Caracas.

Brazil.—At Rio de Janeiro 6 cases of plague and 1 death from the disease were reported between June 22nd and August 23rd.

Chile.—In August several cases of plague reported from Iquique and Autopagasta.

Peru.—Between August 5th and 31st 109 cases of plague occurred with 40 deaths from the disease.

Ecuador.—Two cases and 2 deaths from plague were reported from Guayaquil between July 26th and August 29th.

TRINIDAD.

One fatal case of plague reported on September 30th.

THE BELGIAN ANTITUBERCULOSIS LEAGUE.

The eighth annual report of the Ligue Nationale Belge Contre la Tuberculose contains reports from the provincial branches of the league, as well as the report of the secretary-general.

Antwerp.—The energies of the Antwerp branch were concentrated chiefly on a work of prophylaxis with regard to children, and the Villa Maritime at Wenduyn-sur-Mer was established to receive debilitated children born of tuberculous parents, rickety, strumous, lymphatic, and pretuberculous children, and those with closed tuberculosis. Some pay and others are treated gratuitously, but children from all over Belgium are treated, only provided they have a doctor's certificate recommending change of air; all, however, are charged for their keep. In 1907 the number of children treated was 235. Owing to the generosity of M. le Sénateur Van den Nest a new dispensary was opened, which, when completed, will have a special department for laryngology and radiology, a clinical laboratory for the examination of sputum, etc., with a complete equipment for the analysis of milk, douche baths, and a large lecture hall. During the year five conferences were held, and a committee of ladies collected money to equip the dispensary and the maritime hospital with linen. The ladies are now studying the question of the provision of a special open air sanatorium for the women of Belgium, for whom up to the present little has been done. At the dispensary 3,493 attendances were made; 517 new cases were seen, and of these 72 men, 40 women, and 41 children were recognized as tuberculous. The home conditions of 133 of the 153 new cases of tuberculosis were inquired into. In the majority there was overcrowding, and in one-third the conditions under which they lived were found to be insanitary. Some interesting tables are given. Of the 153 cases, 123, in addition to 230 old cases, received assistance. The following were distributed:

Milk and kefir	47,210 litres.
Bacon	1,260 kilog.
Peas	1,400 "
Rice	1,400 "
Emulsion of cod-liver oil	400 litres.

Also mixtures, dentifrices, toothbrushes, spittoons, and clothing.

In the laboratory 125 analyses of milk and 459 of urine were made, and 421 specimens of sputum were examined bacteriologically. At the Villa Maritime of Wenduyn-sur-Mer 235 children were treated during the year.

Malines.—The Dispensary Hector Leblus was visited in 1907 by 102 fresh patients, 70 of whom were suffering from diseases of the respiratory organs, and of these 23 were definite cases of tuberculosis. Practical assistance was given in the shape of: Milk, 1 882 litres; eggs, 7,224; bacon, 945 kilog.; smoked meat, 24 fillets; cod-liver oil, 8 bottles; rice, 6 kilog.; blankets, 7; beds, 7; lysol, 42 litres; spittoons, 35. Two patients in the Sanatorium of La Hulpe-Waterloo received a monthly sum of 20 francs, and an outfit of 2 flannel shirts, 2 vests, 2 pairs of drawers, 2 pairs of stockings, 1 pair of goshes. The committee has drawn up a plan for the control of farms in order to ensure clean milk. The dispensary has done excellent work in seeing patients and educating them hygienically, and by supplying them with beds in order to isolate them in houses where they shared beds with others.

Brabant.—At the Dispensaire Albert-Elizabéth et Leopold 1,018 patients suffering from tuberculosis were seen. The following help was given: 66,782 litres of milk; 4,065 kilograms of bacon; 2,457 litres of cod liver oil and emulsion; 37,960 kilograms of coal, and 2,697 fr. 50 c. in kind. Entertainments, conferences and lectures with lantern slides were given.

East Flanders.—The figures for disinfection carried on at Gand are illuminating as showing the progress of hygienic ideas:

1897	41 disinfections for tuberculosis.
1898	75 "
1899	82 "
1900	60 "
1901	154 "
1902	208 "
1903	276 "
1904	302 "
1905	292 "
1906	277 "
1907	310 "

The Gand dispensary only diagnoses cases, warns patients of the danger to themselves and to their surroundings and the means of avoiding them, but does not treat. The patients attend periodically, and the accessions are recommended to philanthropic societies for assistance and are given milk by the dispensary. Of the 300 new cases examined in 1907 66 were tuberculous. A disinfecting-room for the linen of tuberculous patients is about to be added to the dispensary, as towns where these exist show striking figures.

Hainaut.—During 1907 over 500 tuberculous subjects have been seen 5,000 times by the two doctors in charge of the dispensary. Seventy-five have been taken in at the Galerie de cure d'air au Bois-d'Havré, and of these 45 per cent. came out cured and able to work as hard as usual.

Limbourg.—Here was held an exhibition of placards, instructive pictures, and leaflets. Here indifference is found among the public and the doctors; nevertheless the propaganda continues and does good, particularly among school teachers, thanks to the zeal of the inspectors. Only three doctors sent patients to the dispensary, where they receive not medical treatment but tickets for milk, eggs, pocket spittoons, leaflets, and the examination of sputa—all gratis. Here the State assists the Bureau de Bienfaisance and the town gives land.

Luxembourg.—Here are held conferences (announced in the newspapers) and lectures, and there is a system of disinfection. The Minister of Agriculture undertakes to train in theory and practice the superintendents and staff in charge of disinfecting centres and to pay half the cost for the equipment of these, while the Conseil Provincial votes 500 francs per annum. They propose next to educate the masses in prophylaxis.

Namur.—Lectures are given, leaflets distributed, and, through the exertions of the local section, the subject was discussed in sixty-five local newspapers. The dispensaries of Namur, Dinant, and Zaminé continue to receive and instruct a large number of patients and to disinfect their houses and otherwise assist them.

Liège.—At Liège the number of tuberculous patients under the prophylactic supervision of the Dispensaire Hortense Montefiore on January 1st, 1907, was 1,143. All degrees of the disease are seen, but it is noteworthy that those in the early stages are far in excess of the more advanced. Of the 286 new cases there were:

213	in first stage, or 74.5 per cent.
44	in second stage, or 15.4 per cent.
29	in third stage, or 7.0 per cent.
9	pretuberculous, or 3.1 per cent.

Of these, 147 were sent by their own doctors, 30 by the patrons of the Oeuvre Liégeoise des Tuberculeux, 34 by other patients, 27 by polyclinics and hospitals, 8 by mutual help societies, and 12 by charitable societies, while 28 attended on their own initiative. Of these patients, 214 were men, 66 women, and 6 children. These 286 cases belonged to households containing a total of 1,080 persons, of whom 347 were children. Of these, there slept in the same room:

85	with 1 other person
57	" 2 other persons
41	" 3 "
16	" 4 "
8	" 5 "
6	" 6 "

154 slept in the same bed with others.

Of these 286 cases, 117 were sent to the sanatorium of Borgoumont, the expenses being borne by:

Mutual aid societies	...	44 patients
Civil hospitals of Liège	...	35 "
Municipal administration	...	26 "
The patients themselves	...	9 "
The employers of sick workmen	...	9 "

After the patients leave the sanatorium they are watched by the dispensary. The experience of eight years proves that the sanatorium and dispensary are complementary, and work harmoniously: 190 old patients from Borgoumont have been under observation. Of these, 177 were in the first stage, 39 in the second, and 4 in the third. Three years after their discharge 65.2 per cent., or two-thirds, appeared to be cured and at work as usual. In 11 per cent. the tuberculosis continues its evolution; the others are dead. In 1908 30,119 litres of milk and 24,297 eggs were distributed, and there were 98

disinfections in 1907. An endeavour is made to isolate infectious cases in the homes; they remain under the supervision of the dispensary, but are treated by their own doctor, the municipality paying; 49 cases were thus isolated in 1907. They were supplied with bed and bedding and the necessary accessories, and the rent of the extra rooms was paid by the Oeuvre. There will shortly be opened, owing in great measure to the liberality of M. Georges Montefiore, a sanatorium for women in the Province of Liège—the first in Belgium.

Verviers.—In 1907, of 173 dispensary cases, 60 had tuberculosis; 15 of these died during the year; 28 were sent to Borgoumont; pocket spittoons were given to all patients belonging to mutual assistance societies, and they also received milk, eggs, and assistance in paying their rent and the disinfection of their houses.

Huy.—In 1907, of 26 new patients, 11 men were sent to Borgoumont and 1 girl to the sanatorium Sainte-Marie at Bornemville; disinfection was carried out, and pocket spittoons, bedding, travelling expenses, rent, clothing, etc., supplied by the dispensary; 76,248 litres of milk, 12,000 eggs, and 1,461 kilos of meat were distributed.

Waremmé.—The antituberculosis dispensary of Waremmé was established in 1907 by the University Extension of Waremmé. The committee, after opening a dispensary, circulated 10,000 leaflets and caused them to be read out in elementary and secondary schools. In 1908, 52 patients were in attendance, showing the importance of the work.

LITERARY NOTES.

IN a note on the art of healing among the Druids, which appeared in the BRITISH MEDICAL JOURNAL of December 26th, 1908, it was stated that among the plants used for their supposed magical attributes was ivy. This should of course have been the mistletoe, which, as every school-boy knows and many schoolgirls learn about this season, was looked upon as having a peculiarly sacred character by the Druids.

Minerva Medica is the title of a new medical review, the first number of which has just appeared in Rome. We are gratified to learn that several of the abstracts, not only of original articles but of some of the lighter notes, are taken from the BRITISH MEDICAL JOURNAL.

Pathologia is the title of a new fortnightly journal published at Genoa, under the direction of Professors Golgi of Pavia, A. Lustig of Florence, A. Bonino of Padua, B. Morpurgo of Turin, G. Tizzoni of Bologna, and a number of other well-known Italian pathologists. The editor is Professor M. Segale. As its name imports, the new periodical is devoted to pathology, and the names of those under whose auspices it appears are sufficient guarantees of the scientific value of its contents.

The *Edinburgh Medical Journal* for November publishes the introductory address of Professor F. M. Caird on his taking possession of the chair of clinical surgery as Regius Professor in the University of Edinburgh. It is entitled *Some Points in the Evolution of Surgery*, and is in fact a very interesting sketch of the history of medicine in Scotland. The Edinburgh School of Medicine dates from 1505, when that "Rycht Potent Prince" King James IV granted a Charter of Incorporation to the Civic Guild of Chirurgians and Barbers, which was the precursor of the Royal College of Surgeons. For a long time, however, there were no men of mark in medicine in Scotland such as the Linacres, the Wisemans, and the Sydenhams who flourished south of the Tweed. "Surgery was rude in a rude age; medical skill and treatment generally beneath contempt," Professor Caird quotes Dunbar's lines on a friar, who was a peripatetic practitioner:

In Scotland than, the nearest way,
He came, his cunning till essay,
To some men there it was no play,
The proving of his science.

He had some notions of anatomy, for we are told "Vein organs he full cleanly carrit." He dispensed his own drugs, and made experiments therewith on the bodies of his patients, for it is said that "In pottingyrie he wrocht great tyme; he murderit into medicine." His handy-work as a surgeon is described as follows:

His trowns were rude as any ranchter,
Where he let bluid it was no lauchter,
Full many instruments for slaughter
Were in his gortyians.

He bled his patients figuratively as well as physically:

In leechcraft he was homicide
He would have, for a nicht to bide,
Ane hackney and the hurt man's hide,
So meckle he was of myans.

After the Reformation Scots flocked to Holland for medical education which could not be had at home. So scanty was the supply of bodies for dissection in Edinburgh that the "resurrection" of corpses caused riots as far back as 1711. The College of Physicians was founded in 1681, but there was no really systematic teaching till 1726, when the City Fathers appointed four professors of medicine, among them the celebrated anatomist, *Monro primus*. Next came into being the infirmary, which was founded in 1736. In addition to medical and surgical wards, with a spacious and well-lit operating theatre, a ward was set aside for lying-in women. There were twelve cells for the insane, and there were beds for unfortunates and a separate ward for married women "sufferers not by any fault of their own." This latter done by petition of the physicians to keep them from the odium of the common Lock. In 1828 the infirmary was enlarged, and in 1879 the famous building, in which such men as Benjamin Bell, Liston, Syme, Simpson, and Lister had done their work, gave place to the new palatial infirmary. Professor Caird gives extracts from old case-books illustrating the practice of John Bell, "the first and, perhaps, the greatest teacher of clinical surgery Edinburgh ever produced." Coming down to a later day, Professor Caird says that in 1853 so great was the mortality from blood poisoning that certain of the most unhealthy hospital wards had to be cleared out and the patients treated in tents on the green. He goes on:

When Mr. Lister began work in Glasgow, hospital gangrene was rampant. It is now unknown. In 1873 that most charming and able of surgeons, Nussbaum of Munich, was afraid to operate, since every wound became infected, and the mortality rose to 80 per cent. Mr. Spence, in his lectures, 1871, "suspects pyæmia is not so infrequent in private practice as is often stated." And now so great is the change that the advance to the seniors among us the old typical pyæmia, with its hay-scented breath, is little more than a memory. This astounding improvement, it must ever be remembered, took place in the selfsame wards where disaster and calamity formerly prevailed. It is to Lister we owe this transformation and incalculable boon. He established definite principles. We can look back on the unrest which characterized his methods, on the manner in which each change led to another advance in his endeavour to treat the surroundings of the wound rather than the wound itself. We admire the beauty and ingenuity with which he defended his wounds from microbes, and yet screened the defensive power of the tissues of the body, on which he so sagely relied, from the agents he employed in combating the microbes. The principles laid down by Lister remain unchanged. The endless striving after perfection which characterized all his methods will never cease.

We commend this passage to the special attention of those who are striving to make believe that Listerism died with the spray which was a passing phase in the evolution of the doctrine. Another passage in Professor Caird's address is worthy of note. He says:

Huxley, whom we were fortunate enough as students to hail as interim teacher when Wyville Thompson was away on the *Challenger* Expedition—Huxley felt himself compelled to renew his student days and to join the zealous throng which daily followed Lister. He summed up his impressions as he said, "What amazes me, Mr. Lister, is the painlessness of your wounds. You have not only banished those awful scourges which used to afflict our wards, but you have abolished the pain and suffering associated with wounds and surgery."

We submit this testimony of Huxley to the consideration of those antivivisectionists who argue from their own preconceived notions that a wound must be painful.

A SOCIETY of medical jurists and prison medical officers has been formed in Hungary. The President is Dr. Ajtai, Professor of Forensic Medicine.

IN connexion with the public library of Grand Rapids, Michigan, a course of eight lectures has been arranged to be given by representatives of the various municipal boards and departments, showing the work they do and the money they receive and spend for the city. Education, public health, public works, and the work of the mayor and common council are among the subjects to be dealt with, and the example is one which might well be followed in other municipalities.

SEVENTY-SEVENTH ANNUAL MEETING
OF THE
British Medical Association,
AT BELFAST, JULY, 1909.

BELFAST—THE COLLEGE AND HOSPITALS.
QUEEN'S COLLEGE.

QUEEN'S COLLEGE, Belfast, in which the Association will hold its meeting next July, has had a remarkable career. Not yet sixty years old it has been affiliated with two universities, has seen both abolished by Act of Parliament, and before these words are in print it will itself have ceased to exist as "Queen's College," and will have blossomed into an autonomous university.

History.

The college was founded by Act of Parliament in 1845, on the initiative of Sir Robert Peel. It, and the Queen's Colleges of Cork and Galway, were affiliated to the Queen's University, established in 1850.

The college having been founded on parchment, a site for it was chosen on the Malone Road, at the south side of the town, and the plans were entrusted to Sir Charles Lanyon, who succeeded in producing a building which has been a constant pleasure to the eye for sixty years. It would be hard to point out a better example of the successful use of red brick for a large building. Belfast brick has none of the anaemic appearance that characterizes so much English brick; but is a good strong red, toning with time to a very rich colour, which when lit up by the afternoon sun, is really beautiful.

The college opened its doors to students in 1849, and among its first professors were several distinguished men. Thomas Andrews, the professor of chemistry, will always be remembered for his researches in the liquefaction of gases and his study of their critical temperatures. Alexander Gordon, the professor of surgery, was the inventor of the well-known splint for Colles's fracture, and an authority on fractures of the head of the femur. For nearly forty years he inspired generations of students with something of his own wonderful enthusiasm in the use of the senses, and specially the sense of touch, in the diagnosis of surgical ailments. Portraits of both these teachers are to be seen in the Great Hall of the college.

Ever since its doors opened the college has grown and prospered, but in its university relations matters have not always gone smoothly. The Queen's University examined and granted degrees to the students of the three Queen's Colleges, and to them alone, and the examiners were the teachers in the colleges. But for various reasons these colleges were not acceptable to the Roman Catholic

majority in the country, and so in 1879 Parliament abolished the Queen's University and set up the Royal University of Ireland, an examining body like London University, which drew its candidates and examiners from all sources, though mainly from the three Queen's Colleges and the Roman Catholic College in Dublin. But time has proved that such a university is not suited to the tastes of the country, and when the Irish Universities Act of 1908 was passed, the ending of the "Royal" did not evoke any deep grief in the country.

Under the Act two new universities take the place of the one old one, but both are to be teaching universities, and not merely examining bodies. One will be in Dublin, with

a new college there, and the Queen's Colleges of Cork and Galway, now called University Colleges, affiliated with it, and the other in Belfast. At the present time a Commission is sitting, appointed by Parliament to draw up the statutes of the new Belfast University, and till these are published it is not possible to give particulars of the courses of

Queen's College, Belfast, where the Association meetings will be held.

study. But from the public utterances of various members of the Commission, and those who are bound to have influence with them, it is clear that the intention is to establish a real centre of learning and culture, and not merely a science and technical school. The Arts side is sure of a considerable number of students, as it will no longer be possible to take an Arts degree without attending classes, as was the case in the Royal University. The candidates for the ministry of the Presbyterian Church in Ireland pass through an Arts course before proceeding to their theological studies at the Presbyterian College, which is just beside Queen's.

As already said, apart from its university difficulties, Queen's College has always prospered, and never more so than during the twenty-five years that have elapsed since the British Medical Association last met in it. The present head of the college (now Vice-Chancellor of the Queen's University of Belfast), the Rev. Thomas Hamilton, D.D., was appointed President in 1889, and under him a forward movement was soon started. One of the first steps was the throwing open of all classes, medical as well as arts, to women, and experience has fully justified the step. There are this session 87 women students; all prizes and scholarships are open to them, and, indeed, are frequently gained by them.

Recent Extensions.

In 1894 new chemical laboratories were opened, followed

in 1897 by the Students' Union and new physiological and pathological laboratories. In 1901 the President initiated the Better Equipment Fund, which resulted in raising of the sum of £70,000, of which Sir Donald Currie, a Belfast man, generously contributed £20,000. Old students of the college and Ulstermen in all parts of the world sent subscriptions, and the movement was of immense benefit to the college, not only materially, but also from the interest it raised. Before the days of the fund the majority of the inhabitants of Belfast and the neighbourhood looked on the college as a Government institution, with whose support or improvement they had no more to do than they would have in the case of police barracks or post office. Another indirect benefit of the fund was the claim which it established on the Treasury, ready, like Providence, to help those who help themselves. The net result is that in the last three or four years large new laboratories have been thrown open to the students of chemistry, engineering, natural history, physiology, pathology, and pharmacology, while improvements in the existing accommodation have been made in all directions, and are still going on. The teaching staff also has been greatly increased. Since 1890 lecturers have been appointed in ophthalmology, sanitary

This hall has a fine lofty roof and mullioned windows, and its walls are hung with portraits, most of them of past teachers. Here may be seen Dr. Andrews, with his simple gas-compressing plant; Dr. Gordon, with a fractured femur in his hand; Dr. James Cuming, the President of the Association when it met here in 1884; Sir William MacCormac, an old teacher at the Royal Hospital, though not at the college; and Dr. Redfern, who is happily still with us, though retired from active work. He was Professor of Anatomy and Physiology from 1860 to 1893, and during all those years his strong personality dominated the medical school. Whatever else "Queensmen" of those days knew or did not know, they were thoroughly grounded in anatomy, and many a grey-haired man shivers yet as he thinks of the heckling he got from "Peter" when he was found consulting the pages of Gray or Ellis on the insertion of a muscle, instead of dissecting it out!

A side door opens from the hall on to the cloisters, from which the science and medical buildings are easily reached. The Latin class-room, at the end of the cloisters, will be temporarily raised to the dignity of a smoking-room. The junior biological laboratory, reached by a stair from the entrance hall, will be fitted up as a writing-room, and

Queen's College, Belfast: New Science Laboratories, from north-east.

science, and vaccination, and demonstrators, assistants, or readers in practically every subject.

As a result of the opening of the new laboratories, there has developed a vigorous school of research workers in different departments, but specially in the pathological. There a number of young medical men have been engaged for several years past in research work, which has at times been aided by British Medical Association grants and scholarships. The epidemics of typhoid and cerebro-spinal fever from which Belfast has suffered have been carefully studied, especially as regards the effect of the micro-organisms of these fevers on the blood, and it is on the suggestion of these workers that the new Section of Haematology and Vaccine Therapy is to be inaugurated at the Belfast meeting.

In the current session there are about 400 students attending college classes, of whom just about half are medical. There are, of course, many more medical students attending the various hospitals, and not at classes in the college at present.

The Buildings.

On entering the main door of the college the Great Hall is found immediately on the right, and here during the Association meeting will be the general reception-room, post office, etc., with plenty of room and seats for those wishing to look over their letters or chat with friends.

On the same stair will be found the local secretaries' and other offices. In the various lecture rooms and laboratories there will be accommodation for all the sections.

The library is a detached building on the north side of the college, close to the University Square gate. It contains a collection of about 80,000 volumes, which is being rapidly increased now that more prosperous days have dawned, and the building itself will shortly be enlarged by the addition of two new bays. In the library the meetings of Council will be held, and the addresses in medicine, surgery, and obstetrics delivered.

The Students' Union is another detached building at the north-east corner of the grounds, and in it will be the refreshment department, where luncheons and teas will be provided.

In the main block of medical buildings three of the sections will meet, and there the pathological museum will be housed, the medical museum and dissecting room affording ample space for it. In the medical museum will be found the unique collection of fractures which the college owes to the energy and enthusiasm of the late Professor Gordon. The collection is probably without a rival in the world, and will be one of the main points of interest to members of the Surgical Section.

The trades museum will be found in the exhibition hall of the Botanic Gardens at the south-east corner of the college grounds close to the medical buildings.

The Medical School.

From the opening of the college till within the last few years the general clinical teaching of medical students was confined to the General Hospital, afterwards the Royal, and now the Royal Victoria Hospital. But recently the Union Infirmary and the Mater Infirmorum Hospital have been thrown open to students, and certificates from them are accepted by the university authorities. Besides the general clinical instruction, special instruction is given in the two children's hospitals and in the various special hospitals mentioned below.

THE ROYAL VICTORIA HOSPITAL.

Apart from the Union Infirmary, the Royal Victoria Hospital is much the largest hospital in Belfast, containing, as it does, 300 beds.

It originated as a dispensary in 1792, which developed into a fever hospital in 1797 and a general hospital in 1799. In 1817 the old General Hospital in Frederick Street was built, and gradually increased by the addition of new wings to 180 beds. In 1875 it became by Royal Charter the Royal Hospital. As the city grew the accommodation at the hospital became far too small, as well as out of date, and it was resolved to build a new hospital. This resolve in due time took shape, and the new hospital was opened by the King in 1903, being called the Royal Victoria Hospital in commemoration of the Diamond Jubilee.

The hospital is built on a site granted by the corporation, consisting of six acres of the old asylum grounds in Grosvenor Street. The position is not a central one, and it was only after much discussion that it was decided upon, but it was finally concluded that the healthy site on open and elevated ground was sufficient compensation for the long distance from the docks and shipbuilding yards.

The plans were drawn by Messrs. Henman and Cooper of Birmingham, and are of a strikingly original character. The two guiding principles were that all patients should be on one floor, and that the whole building should be heated and ventilated by the plenum system. Consequently all the wards are on the same level, a series

of seventeen running out side by side from the main corridor, the lighting being, with the exception of the two end wards, by lantern lights in the roof, and one large French casement in each ward, at the south end, looking out on the garden and tennis grounds. The wards are on the unit system, arranged in pairs for male and female patients, each unit having 32 beds, and its own ward kitchen, clinical room, or theatre, etc. Each physician or surgeon has his own unit, and his work is thus almost as much separated from that of his colleagues as if he were in a separate hospital.

The only wards not included in the foregoing are the

ophthalmic wards, which are in a small block to the north of the main corridor, and the septic and infectious wards, in two small isolated blocks at the west end. The administrative buildings are on the north side of the main corridor, consisting of a low central hall flanked by two large four-story buildings, as seen in the illustration. The out-patient department is also on the north side, between the administrative block and the ophthalmic wards. There is a large central waiting hall, with eighteen rooms round it for the use of the various departments of work,

and in the basement below is ample accommodation for students.

The pathological block is also on the north side of the main corridor, with a separate entrance, and every accommodation for work. On the west side of the hospital, and entirely detached from it, is a house for the medical superintendent.

The air for ventilation is taken in through a large shaft which rises on the east side of the hospital, and, bifurcating, leads down to two fans, each over 10 ft. in diameter and capable of driving

10,000,000 cubic feet of air per hour. One fan only is needed at a time, the other being in reserve for emergencies. As the air goes to the fans it is washed by passing through wet curtains, and warmed by steam pipes if necessary, and after passing the fans it is carried through a large tunnel under the main corridor, with branches to all parts of the hospital. Provision is made for altering the temperature in any ward by steam pipes at the intake of air for each ward.

After five years' experience the general results of the working of the plenum system are favourable, and neither medical staff nor board of management regret what was looked on by many as an experiment.

THE THRONE CONVALESCENT

HOME AND HOSPITAL is situated on the slopes of the hills to the north of Belfast Lough, about 4 miles from the city. It is under the same board as the Royal Victoria Hospital, but has separate funds. It is a composite institution, and includes a hospital for children—chiefly chronic hip and spine cases—with 33 beds, a consumption sanatorium with 10 beds,

and the convalescent home for patients from the Royal Victoria with 22 beds.

THE MATER INFERMORUM HOSPITAL.

This hospital, situated on the Crumlin Road, on a good elevated site, was founded in 1833, when a house on the present site was bought by the late Dr. Dorrian, Roman Catholic Bishop of Down. In a few years the house was demolished and a handsome new hospital, erected from plans by Mr. W. J. Fennell, M.R.I.A., was completed in 1904.

The hospital is built on the pavilion system, and is

Queen's College, Belfast: Students' Union.

Royal Victoria Hospital: North front showing administration blocks.

planned for 165 beds. The east pavilion has six large female wards on three floors. The west pavilion accommodates the extern department on the ground floor and four large male wards on the first and second floors, while the central pavilion is administrative, and between the pavilions are several smaller wards for children and special cases. At the back of the administrative pavilion is a handsome chapel, and behind it are two large and well-lighted operation theatres. The total cost was about

ample room in the grounds round it for rebuilding and extending it. There is an extern maternity department, and by mutual agreement the County Down side of the city is left to this hospital, while the needs of the County Antrim side are looked after by the next named.

THE MATERNITY HOSPITAL.

This is one of our oldest charities, having been founded in 1794. The present fine hospital in Townsend Street was

Royal Victoria Hospital, Belfast: South-west corner, showing wards, sanitary towers, and large single windows.

Royal Victoria Hospital, Belfast: South front.

£50,000. The nursing is under the supervision of the Sisters of Mercy, but persons of all creeds are freely admitted as patients. Ground has lately been acquired on the east side of the hospital, and a new block is to be erected for the extern department, which has quite outgrown its present quarters. During the present session clinical teaching has been begun, and arrangements have been made for resident pupils.

St. Colman's Sanatorium, near Carrickfergus, is worked in connexion with the hospital for convalescent patients.

HOSPITAL FOR SICK CHILDREN.

This charity was founded in 1873, and the present hospital in Queen Street was built in 1879. On the ground floor are the board room, dispensary, etc., and on the first and second floors the surgical and medical wards, with 20 beds in each.

Good use has been made of the rather cramped city quarters, and as the hospital is on the edge of the poorest and most crowded district of the city it has ample scope for work. Much larger quarters could easily be occupied if available.

ULSTER HOSPITAL FOR CHILDREN AND WOMEN.

This hospital, originally near the other children's hospital, was moved to Templemore Avenue, Mountpottinger, on the County Down side of the river, some eighteen years ago. As it is the only hospital in that enormous working-class district it is always full to overflowing. There are at present 8 beds for women and 20 for children, but a movement for rebuilding the hospital is in progress, and, no doubt, when that materializes the accommodation will be greatly increased. More than half of the necessary sum, £10,000, has been promised, but it has been arranged that no building shall be started till every penny is contributed. The present premises are simply an old house, once a suburban villa, converted to hospital use, but there is

opened in 1905 and gives accommodation to 24 women. The general arrangements for work are excellent, and the hospital is well worthy of a visit from all who are interested in obstetrical work. About 500 to 600 women are delivered annually in the hospital, and a larger number attended in their own homes.

OPHTHALMIC HOSPITALS.

There are two special hospitals for the treatment of eye,

Royal Victoria Hospital, Belfast: A surgical ward showing roof light and single south window.

and throat cases—the Belfast Ophthalmic Hospital, in Great Victoria Street, founded in 1867, and the Ulster Eye, Ear, and Throat Hospital in Clifton Street, founded in 1874. Both have crowded externs on most mornings of the week, and wards generally full, so that there seems to be ample work for both, as well as for the special departments of the general and children's hospitals.

THE SKIN HOSPITAL

will be found in Glenravel Street, off Clifton Street, close by the last mentioned ophthalmic hospital, having been founded by the same generous family—the Bennis. In accordance

with the original plan of the founders, accommodation is provided for a number of private patients in both hospitals. The extern department of the Skin Hospital has lately been remodelled and equipped with all modern apparatus.

THE SAMARITAN HOSPITAL.

This hospital, situated on the Lisburn Road, not far from the college, was, like the two last-named, built by the Benn family. It was opened in 1874, and in 1897 two cancer wards were added through the generosity of the late Mr. Forster Green. There are 25 beds, and about 1,000 outpatients are seen annually.

FORSTER GREEN HOSPITAL FOR CONSUMPTION.

In 1873 several medical men in Belfast started a special

dispensary for diseases of the chest. This developed into a small hospital with 6 beds in 1890. It was in an old city house, most unsuitable for the purpose, but it served to show the necessity for such an institution, and when efforts were being made to improve matters, the late Mr. Forster Green came to the rescue, and bought a beautiful house and forty-five acres of ground at Fortbrida, about ten minutes' walk from the end of the Ormeau Road tramline. After extensive alterations this was opened with 40 beds, and every arrangement for open-air treatment. The Belfast Corporation has lately arranged to endow 30 additional beds for a period of ten years at least, and new wards containing these beds were opened in 1903. All arrangements are on the most approved modern principles. The grounds, which are well wooded, with beautiful views of the Antrim Hills, give ample space for exercise to those patients who are allowed it. There is a resident physician, and a small but very practical little laboratory is provided, where he or the visiting staff can examine sputa, etc. In connexion with the hospital is a city dispensary open on three days a week, and a nurse who visits patients in their own homes and acts as a fresh air missionary.

THE ABBEY SANATORIUM.

Some two or three years ago the Belfast Board of Guardians found the consumptive wards in the Union Infirmary so crowded that they decided to open a special hospital and sanatorium to relieve them. A fine old country house with good grounds was then on the market

Forster Green Hospital for Consumption.

—the Abbey, at Whiteabbey, on the north shore of the Lough, about five miles from the city. This was purchased, and the house was fitted up as the administrative block and hospital for more advanced cases, while accommodation was provided in pavilions in the grounds for cases which were suitable for sanatorium treatment. In all 265 cases are at present under treatment, the full number for which there is room, and the results have been such as to thoroughly justify the guardians' enterprise. The provision of two new pavilions is under consideration, as numbers of applications for beds in the sanatorium have to be refused. All the arrangements are excellent, and the insti-

tution well merits a visit. Though much remains to be done to combat the scourge of tuberculosis, it must be admitted that, compared with other cities of its size, Belfast has some reason to be pleased with the fact that it has in the Forster Green, Abbey, and Throne Sanatoriums about 350 beds devoted to the treatment of this disease on modern lines.

THE FEVER HOSPITAL.

The Fever Hospital, with 168 beds in six pavilions, and the District Lunatic Asylum are at Purdysburn, about six miles from the city, and two from the tram terminus. The villa system has been adopted with great success at the asylum, and both institutions should be visited by those interested in the lines of work carried on in them.

THE MEDICAL INSTITUTE.

The Ulster Medical Society, which began its existence by the amalgamation of two older medical societies in 1862, and which includes in its membership most of the medical men of Belfast and the neighbourhood, is proud and happy in the possession of a home of its own. For years the society had met in the Royal Hospital, the Natural History Museum, and various other places, and every now and then there was a talk of starting some scheme for providing it with a permanent meeting-place with proper room for its library, but the financial and other difficulties seemed insuperable. The difficulties, however, were overcome as completely as unexpectedly. At the annual dinner of the society in 1901 the President, Sir William Whitla, offered to build and furnish the desired home, provided the society paid the ground rent and

A Ward in Forster Green Hospital.

undertook the upkeep of the premises. The scheme was unfolded in detail, accepted enthusiastically by the society, and a central site was secured in College Square North. The foundation-stone was laid in April, 1902, by Professor Redfern, and the building opened by the Lord Lieutenant of Ireland in November of the same year.

The building has a frontage of 50 ft., and is three stories high, of rough-hewn white stone, with doors and windows relieved by red sandstone worked in Gothic moulding. Over the top gable stands the serpent coiled round the rod of Esculapius.

On the ground floor are two large rooms separated by

glass doors; the smaller is the entrance hall and smoking-room, and the larger the library. When desired, the doors can be removed and the two rooms thrown into one. Over the fireplace in the entrance hall is a marble bust of Sir William Whitla, subscribed for by the members of the Society. Over the library fireplace is one of the features of the institute—a large window, whose sill forms part of the stonework of the chimney-piece. It contains a beautiful stained-glass memorial to the late Dr. William Smyth, of Burton Port, co. Donegal, and was unveiled by Her Excellency the Countess of Dudley on the afternoon of the day on which the Lord Lieutenant opened the institute. In a very touching speech she paid her tribute of admiration to the man who, when all others refused to help, carried food and medicine to the people of the typhus-stricken island of Arranmore, off the coast of Donegal, and who finally lost his life from the same fever, contracted by carrying some of the patients, with the help of Dr. Brendan MacCarthy, to an old boat, and rowing them to the mainland. Lady Dudley well described him as an everyday hero, wholly unconscious of having performed any unusual act of heroism. The panels of the window show two scenes of the story—one of Dr. Smyth kneeling by the bedside of an Arran fisherman, and the other of him and Dr. MacCarthy with a sick

girl and her father in the boat. Across the base of the two panels are the words, "Inasmuch as ye did it unto these." Behind the entrance hall and library

Medical Institute, Belfast. Built and presented to the Ulster Medical Society by Sir William Whitla.

are cloak-rooms and a small committee-room. On the first floor is the large hall for society meetings, 45 ft. long, 33 ft. wide, and 17 ft. high, with a musicians' gallery near one end. This hall will seat nearly 200 and will dine about 120. It is fitted with double windows to deaden outside noises, and has facilities for various methods of illustrating lectures. Two portraits have already been presented to it, and no doubt in time others will be added.

Behind the hall is the steward's kitchen and pantry, with facilities for serving dinner. By express wish of the donor no alcoholic liquors may be brought into the institute for the use of members except at the annual dinner or similar official gathering. On the second floor is a large billiard-room and the steward's apartments. The whole was built and equipped at a cost of about £8,000, and handed over by the donor to seven medical men to hold in trust for the Society. No rivalry exists between the Ulster Medical Society and the Ulster Branch of the

British Medical Association or its Divisions, and every facility is given to them for holding their meetings in the institute.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT.

(Continued from vol. 41, 1908, page 1870.)

We continue our abstracts from the evidence of which the minutes are contained in the fourth report of the Royal Commission on Vivisection, issued in December, 1907.²

ANTIVIVISECTIONIST TESTIMONY.

Evidence of Sir George Kekewich, K.C.B., M.P.
(continued).

In regard to serums, they would be inclined to hold that more lives had been sacrificed by the introduction of these than if they had not been used. They had an instance in Koch's tuberculin. Asked what made him take 1729 as the year that he started from in regard to influenza, he said that was the first record of the invasion of influenza. He did not know that a particular bacillus had been discovered, but he was aware of the theory that the bacillus was not the *causa causans* of zymotic diseases generally. As he understood the theories, one was that the bacillus was the cause, the other that there was a poison surrounding the bacillus on which the bacillus fed, and that the bacillus was really a cleansing and curative agent. Asked by Sir William Church in regard to antipyrin and sulphonal, he said he was informed that antipyrin was very seldom prescribed now because of its effect on the heart, and that sulphonal was also not prescribed generally because of its cumulative effects. He got the information from a member of the medical profession. Asked if his informant told him that he did not use them, but that he probably used bodies closely

resembling them which had also been introduced of late years, he said that he did not know. Asked as to his statement in regard to mice with tumours ("We are not told of means taken to restrict the growth"), whether he had ever made any inquiries as to what was done with mice when the tumours became large, he said he did not know that his association had ever either written or asked the Cancer Research Fund anything about the mice, or ever asked to be allowed to see them. Asked what led him to state that "there must necessarily, upon waking up from anaesthesia" (that was after operations on man), "be very severe and prolonged pain until the severed tissues heal," he said that was in the extensive cutting operations, with excision of organs. He should have thought that any ordinary layman would know that. Proceeding, he said the *précis* put in by him was prepared by the Parliamentary Association generally and their executive, and there were on it several members of the medical profession. He did not wish to mention their names. Mr. Stephen Smith was not one. Miss Arabella Kenealy was one and Dr. Bouchier, and he thought some others. In reply to further questions, the witness said he understood that the sanitary method of combating the disease was not taken to a very large extent in India—not to the extent, at all events, that it had been taken in Egypt. He took it that it was a great deal more difficult to effect complete sanitation in India than in a country like Egypt, which was more closely governed. He thought the people of India, whatever the Government might think, were gradually becoming converted to the view that he held, that the inoculation was actually causing plague amongst them. He had not heard that it was the attempt to put the rules of sanitation in force that had caused the unrest. He was not arguing merely that if they had taken measures of sanitation in India to the same extent that they had in Alexandria they would have stamped out the plague. He was rather arguing that if they had left things

² London: Printed for His Majesty's Stationery Office, by Wyman and Sons, Limited, 109, Fetter Lane, E.C. And to be purchased, either directly or through any bookseller, from Wyman and Sons, 109, Fetter Lane, Fleet Street, E.C.; and 32, Abingdon Street, Westminster, S.W.; or Oliver and Boyd, Edinburgh; or E. Ponsonby, 115, Grafton Street, Dublin. (1908.)

alone without the introduction of Haffkine's serum, the plague would have burnt itself out. Asked if other serums acted in the same way, he said he presumed that they produced disease in a modified form, otherwise no immunity would be conferred. Asked if his association had taken any trouble to inform themselves on that question, he said he had no doubt they had, but he could not possibly tell everything that the association had done. It was put to him that he had brought forward the plague in India as an instance without having any personal knowledge of the subject, and apparently without the association having taken very great pains or labour to investigate the subject. The witness replied that he did not admit that at all. He admitted that he had not had any experience from the point of view of a medical expert. Asked by Sir Mackenzie Chalmers if he had read the evidence of Dr. Martin, who had inoculated himself twice or three times, he said, No. Asked by Sir John McFadyean to what extent he had exercised his power of observation in judging as to the possibility of anaesthetizing animals sufficiently, Sir G. Kekewich said he did not mean observation in the sense that he had witnessed experiments on animals, for he had not. He was rather referring to observations that one had of pain in animals. It was then put to him by Sir John McFadyean that the Commission had had before it the President of the Royal College of Surgeons and the President of the Royal College of Physicians, and representatives of most of the universities, and a great many other medical men, and that they had been almost unanimous in their opinion that great advances had been made in medicine and surgery within the last fifty-five years, and most of them held that a great deal of that advance was due to experimentation on animals. The Commission had to weigh against that the evidence of the witness and that of a smaller number of persons, most of them non-medical, and he asked if the witness thought they would be violating the principles of common sense if they accepted the opinion of the majority in this case. The witness replied that one distinguished surgeon who was examined said he had rejected remedy after remedy until his remedies had been reduced to a number that he could count on the fingers of his two hands. That was Dr. Bantock. He had no doubt that he was one of the minority. Another answer he might make was that the fact that the majority was in favour of a thing was absolutely no proof that their opinion was right. That had been shown in medicine more than in almost any other line—more even than in politics. There was just as much common consensus of opinion in the medical profession years ago in favour of Lord Lister's antiseptic treatment of wounds; and as he understood at the present day Lord Lister himself had given up his antiseptic treatment. Sir John McFadyean said they had had evidence from distinguished surgeons who had scouted the view that the witness had just put before them, and they had really had no respectable evidence to show that what he had said was true. The witness said he could give other instances. In former days the medical profession was uniformly in favour of blood-letting and strong purgative treatment by calomel. All that was gone. Inoculation for small-pox was another instance, and that was gone, and yet it was supported by the great majority of the medical profession. His only point was that the majority were not always right, neither were they often right. Asked if he suggested that it was possible under the existing law and under the Act to experiment on animals for the purpose of instructing students without the use of anaesthetics, throughout the whole course of the experiment, and without killing the animal at the end of the experiment, the witness said, "Without killing the animal at the end of the experiment? I do not see in this Act any provision of this kind." Asked if he would take it that the Commission was satisfied that that was the state of the law, Sir G. Kekewich said he was not satisfied himself. He thought that any body of young men witnessing a series of experiments involving horrible cuttings of animals and practices of that kind would become degraded. In reply to another question, he said he had very great doubts whether man had the right to kill one of the lower animals. He knew perfectly well that it was possible to anaesthetize an animal under experiment. What he was in doubt about was whether as a uniform practice complete anaesthesia was obtained. There was a

great deal of evidence that one had read in different places to the effect that complete anaesthesia was not obtained in these cases. He remembered seeing a series of lectures by Professor Crile, in the course of which it was shown by his own admissions that the animal did wake up and move its legs and its body. There was also evidence in a very considerable number of cases that the animals were not fully anaesthetized, and that the anaesthetizing was left to very incompetent hands. Asked if that meant that there was some difficulty in causing continuous efficient anaesthesia to animals like dogs, or if it was that there was a deliberate evasion of the Act, the witness replied that he took it that there were cases of both kinds. Asked to cite a case in point, or half a dozen, he said he could not carry these cases in his mind, but he certainly had read of a good many cases in which the anaesthesia was not complete. Miss Lind-af Hageby affirmed that "the most unsatisfactory and obviously unreliable methods of anaesthetizing are in vogue in the vivisectional laboratories." That was the kind of evidence.

The following cases were subsequently forwarded:

1. In the *BRITISH MEDICAL JOURNAL* for November 10th, 1906, Dr. W. G. McCullum, recalling previous experiments, writes: "It will suffice to recall to your memory the fact that in dogs, cats, rabbits, monkeys, and many other animals complete parathyroidectomy is followed within a few days by the condition commonly described as tetany, in which convulsive spasms and rigidity of the muscles of all parts of the body render the animal almost helpless. Respiration becomes exceedingly rapid and laboured, profuse sweating occurs, and death supervenes in the attack, although occasionally the violent symptoms gradually give place to a stuporous condition which may last several days, terminating in death."

2. In Kirkes's *Halliburton's Physiology*, fifteenth edition, p. 287, it is stated: "Another experiment, originally performed by Salathe, can be demonstrated on a 'hutch rabbit.' If the animal is held by its ears with its legs hanging down it soon becomes unconscious; and, if left in that position for about half an hour, it will die."

3. In Dr. Crile's experiments upon "shock" the foot of a fox terrier was crushed under "incomplete anaesthesia." Dr. Crile states also in his book that when he applied flame to a dog's paw "the animal struggled on the application of the flame."

4. Professor Schafer experimented in drowning and resuscitating 36 dogs (2 without anaesthetics at all).

5. In a paper read at a meeting of the British Medical Association, at Toronto, Professor Cushny described a number of severe abdominal sections which he had performed upon dogs, cats, and rabbits to which no anaesthetic, but merely morphine, urethane, and paraldehyde had been given.

6. In the *Journal of Physiology* for August, 1906, in a paper on the Functions of the Thyroid and Parathyroid Glands, Professor Svede Vincent and Mr. W. A. Jolly, Assistant to the Professor of Physiology in the University of Edinburgh, record a number of experiments on monkeys, cats, dogs, prairie wolves, badgers, and rats from which the thyroid and parathyroid glands had been completely removed. They state: "Dogs, cats, foxes, and prairie wolves frequently suffer severely and die."

In reply to questions as to the evidence given by Mr. Hobday with regard to the case with which animals might be anaesthetized and kept under anaesthetics for a long period, the witness said he was bound to believe what he said. He had always understood that morphine was used to deaden pain, but that it did not act as an absolute anaesthetic or stop pain, unless, indeed, it was given in an excessive dose so as to induce insensibility. Asked if he knew of any instances in which hideous torture had been caused under the Act, the witness said surely where experiments were performed without any anaesthesia there must be hideous torture. Asked if he knew of any case in which hideous torture had been caused by any experimenter in this country under the Act, he answered that it was impossible, under the conditions specified, that hideous torture should not be caused. It was very difficult to give any case of hideous torture, because, after all, the only fair witness as to hideous torture was the animal itself, and one could not examine the animal. With regard to influenza, what he said was that in 150 years the medical profession had not discovered either the cause of influenza or how to cure it. Asked if that was a failure to discover something by experimentation, or if he wanted to prove that it was impossible to learn anything by observation either, he said he thought they could learn more by observation—that, in fact, it was the only reliable source of information. Asked to explain how it was that this fact discredited experimentation but did not discredit observation, he said the medical profession

had discovered nothing about influenza, as to either its cause or its cure, by observation; but since they adopted experimental methods they had not succeeded in discovering anything more. Asked if he had ever heard of human influenza affecting any animal other than man, he said he never had, but he should have thought it could be communicated to animals. Asked by Sir Mackenzie Chalmers if he had inquired into it, he said he had no knowledge that influenza had been communicated to animals. In reply to further questions, he said that if influenza could not be communicated to the lower animals, and therefore could not be made the subject of experiments, he admitted that under those circumstances one might be wrong in saying or implying that the failure to discover the cause or the cure of influenza was in any way due to the failure of experiments on animals. Asked by Sir Mackenzie Chalmers if, when he said his association was anxious to abolish vivisection, he meant cutting operations on any animal experiments, he said the difficulty as to experiments was that there might be experiments in feeding or other innocuous experiments. They wished to abolish all experiments involving cutting or inoculation with any disease. That would include the use of animals used for the preparation of vaccine and the use of animals used for preparing antitoxin. Asked if he objected personally to using calves for the preparation of vaccine, he said he objected to vaccination altogether and also to antitoxin for diphtheria. Asked if his association would wish to prohibit mutilations of animals for commercial purposes, he said that gelding a horse was not an experiment. It was a matter of long custom. He would not, for instance, put down circumcision among the Jews. Asked if he would require it to be done under an anaesthetic, he said he really did not know that it was a sufficiently serious operation. He was afraid Moses did not use anaesthetics. Spaying cows would be on the same footing as gelding horses. In reply to further questions, he said he did not deny for a moment that inoculation might give a mild attack of plague and give immunity for a certain time. All that he desired to enforce was that these people who were inoculated might give the plague to others. Asked if he had considered how far plague was infectious or contagious, he said he had never observed cases of plague, but so far as one's reading went, one was in very great doubt as to what the means of communication of plague were. What between rats and fleas, and all the rest of it, one did not know any more than one did with many other diseases. Asked how he accounted for the fact that all the heads of the medical profession were unanimous in favour of the necessity of animal experimentation, he said they looked at it through medically coloured spectacles. He did not mean to say that they were not honestly biased by considerations of so-called humanity. He agreed that they were the people who were in daily personal contact with disease, and therefore had more means of judging than others. Mr. Ram asked if the witness could suggest any reason why the heads of the profession and those who represented the universities and royal bodies, should wear glasses of one colour, and those who wore glasses of another colour should be few and not distinguished, the witness said he was not drawing a distinction as regards glasses between those medical men who were in favour of experiments upon animals and those medical men who were not. He was drawing a distinction between the medical profession generally and the general public. On Mr. Ram pressing the question how he accounted for the fact that all who were eminent were on one side and those that were not eminent and few in number were on the other side, the witness said they were not undistinguished on the other side. Surely Dr. Bantock was a very distinguished and very successful surgeon. Mr. Ram pointed out that Dr. Bantock gave evidence in favour of the necessity of vivisection, and again asked why it was that all the most eminent men advocated the necessity of experiments, if it was a fact; as the association thought, that experiments were useless. The witness replied that he really could not say why they all did. He imagined that they were perfectly honest in their view, but he imagined that the general public and the parliamentary feeling which they represented very largely had a right to their opinion. They looked round them; and they did not see

any great advantage having been gained by these experiments, and they did not see that disease was less or that the population was becoming less degenerate. In reply to further questions, he said he did not think that medical science had much advanced since the time when he was a boy. Sanitary science had improved enormously. He thought great advances had been made in surgery, but he believed those advances to have been made by operating on the dead body and observation of the dead body, not on animals. Asked how operations on the dead body differed now from what they were fifty years ago, witness said he meant that our knowledge had come from operations on the dead bodies of human creatures rather than upon the living bodies of animals. He admitted that a great advance had been made in the treatment of wounds afterwards. Asked why it was more demoralizing to examine an animal under an anaesthetic from which it never could recover than to examine an animal which was dead, he said because to a layman the cutting and wounding and mutilation of living animals was the most sickening process one could possibly imagine. He felt it would be most demoralizing to him. Asked if he had any instance he could give of any person who to his knowledge had been demoralized or adversely affected morally after having performed experiments on living animals under anaesthetics, he said he did not think he could give any specific instance of any man who by indulging in experiments on animals had become a thief or a murderer, or even in other senses immoral. Asked if he could cite an instance of man becoming callous or inhumane, he said he could not imagine that any man could go through all those experiments without becoming demoralized. Pressed whether if he could tell of any man who, to his knowledge, had been adversely affected, he said of course he could not. If he did know of a man he would not be able to tell of him. Mr. Ram said he took that the answer was that he did not know any concrete case of that kind. The witness replied, Certainly. Asked by Dr. Gaskell if his association or himself during the whole of that year (since Professor Starling gave evidence on December 12th, 1906) had made any attempt whatsoever to accept Dr. Starling's invitation to visit his laboratory, he said, No, because they would be of no use. It was put to him that he had said that a man of common sense and intelligence, as he considered himself, would be able to judge on the subject as to whether a dog was properly anaesthetized or not. The witness replied, Yes, but in order to do that, what he would like to do would be to be able to see through a hole in the door without its being known that he was there. He did not say that there would be anything underhand or wrong about it, but he did say that if an observer was present special care would be taken. If they could get admission for a doctor whose views were in accordance with their own to see these experiments they would be very glad. For instance, there was a Dr. Hadwen who was very prominent in anti-vivisection societies. If they could get admission for him they would be very glad. If they could get admission for Miss Lind-a-Hageby he dared say it would be very useful to them, but for a mere member of Parliament or layman to go and witness experiments would be of uncommonly little use. In reply to Dr. Wilson, he said that on ethical grounds alone he would press for the total abolition of vivisection.

THE annual dinner of the West London Medico-Chirurgical Society is to take place at the Wharfedale Rooms on February 12th.

UNDER the will of the late Miss Sarah Elizabeth Grumbridge of Brighton, the Brighton Eye Hospital and the Sussex County Hospital each receives a sum of £500.

THE twelfth International Congress on Alcoholism is to be held at the Imperial Institute, South Kensington, from July 18th to 24th, 1909. The Duke of Connaught has accepted the office of honorary president, and there is a distinguished list of vice-presidents. There will be general meetings each morning, as well as sectional meetings in the afternoon or evening, and an exhibition of publications and apparatus will be arranged. Further information can be obtained on application to the Honorary Secretaries, 34, Paternoster Row, London, E.C.

PROPOSED LEGISLATION ON ANAESTHESIA.

The attention not only of the profession but of the public has during the past year or two been drawn to the subject of the administration of anaesthetics by the number of deaths which have occurred under their influence. A report of an important debate on the subject will be found in the *Transactions* of the Medico-Legal Society for 1907-8.¹ Dr. Hewitt moved that the two following motions should be forwarded in the name of the Medico-Legal Society to the General Medical Council and to the Privy Council respectively:

1. That in view of the importance of the administration of anaesthetics, this Society is of opinion that it is highly desirable, in the public interest, that every member of the medical profession, before he is registered, shall have received instruction in the administration of anaesthetics. It therefore earnestly begs the General Medical Council to consider whether they can see their way to include a course of instruction in anaesthetics amongst their requirements in regard to professional education.
2. That as the administration of any drug or drugs with the object of producing generalized insensibility to pain or actual unconsciousness for any medical and surgical purpose, or during childbirth, cannot be safely undertaken without medical knowledge and skill, your petitioners humbly pray that legislation be granted whereby the administration of any drug or drugs with either of the aforesaid objects by any person other than a duly-registered medical practitioner or someone acting immediately under his supervision, direction, and instruction be made a penal offence.

He said that it appeared that any person, qualified or unqualified, experienced or inexperienced, might administer an anaesthetic; and provided he did so to the best of his ability and with no unlawful motive, he was not likely to be punished or even blamed if death occurred. The General Medical Council did not make a course of instruction in anaesthetics one of its requirements, though it recommended that some instruction should be given. Dr. Hewitt said he had written recently to the twenty-two examining bodies of England, Scotland, and Ireland, and he found that only eight made it compulsory for candidates to have received any instruction in anaesthetics. The Society of Anaesthetists had, he believed, approached the General Medical Council, and had been told there was no room for another subject. Dr. F. J. Smith said that he thought the second motion contained a pious opinion which, he was afraid, would go the way which good intentions were said to go. He could not imagine the Legislature passing anything like an Act based on those lines, or interfering with quackery, of which perhaps nineteen-twentieths of its members availed themselves. He contended that if a man did his level best he was not responsible for any particular catastrophe. He protested against coroners holding inquiries in such cases. Professor Glaister of Glasgow said that during the last ten years he had made *post-mortem* examinations of the bodies of sixty-one persons who had died during the administration of anaesthetics, and he believed the number was greater than that. He was afraid the Legislature would be slow to give effect to the resolution before the meeting. He was inclined to believe that chloroform, instead of being a safe drug, was one of the most uncertain in its influence on an individual, because the factor which was not constant in the equation was the person to whom it was being administered. The statement that a large proportion of deaths under chloroform might be prevented must be received with caution. Dr. C. Templeman of Dundee said that at St. Andrews no student was allowed to graduate without having had several opportunities under skilled supervision of the administration of chloroform, but no certificate was required. All cases of death under anaesthetics in Scotland were inquired into by the Procurator-Fiscal. Dr. Waldo, Coroner for the City of London, and for Southwark, said that the reports of the Registrar-General of England and Wales for the five years 1902-6 gave a total of 786 deaths under anaesthetics used for operations, being an annual average of 157 deaths. In about a quarter of this number the anaesthetic given was not indicated. The sources of the Registrar-General's statistics were said to be (1) the coroner's certificate of the finding of the jury and (2) death certificates by

medical practitioners. As regards the coroners' returns, Dr. Waldo said the practice of individual coroners differed. Some held inquests in all cases reported, whilst others selected particular cases for inquiry, notwithstanding the recommendation of the Coroners' Society in 1903 that "inquests should be held on all deaths occurring whilst under the influence of an anaesthetic, irrespective of whether the friends or of those specially concerned in the administration of the anaesthetic and the operation were satisfied or not." He added that, as regards the notification of deaths under anaesthesia by medical practitioners, these appeared to be almost entirely connected with deaths in public hospitals. The medical man, he said, was not compelled by any statutory obligation to report deaths under anaesthesia to the coroner, although, it would seem, he was bound by common law to report all deaths of a violent or unnatural character. The result was that the statistics of deaths under anaesthesia were practically of no scientific value. Among other suggestions made by Dr. Waldo was the appointment of a Royal Commission, with advisory powers, to inquire into the present facts of death under anaesthesia, together with all the official machinery for registration. Mr. Hubert Sweeney, Barrister at Law, held that, even when the medical man did his best, he should not be entirely exonerated from responsibility. As regards the suspicion which resulted from inquiries, he said suspicion would be ten thousand times greater if there were no coroners' inquests. The President, Mr. Justice Walton, agreed with Mr. Sweeney. In regard to inquests, the law was perfectly simple and plain. The difficulty arose from the facts. The law said that a coroner must hold an inquest if he thought the death was an unnatural death. The coroner was the judge, and if he had reason to think it an unnatural death, he must hold an inquest. That involved various questions. To apply it to death from anaesthetics, in the first place there must be reason to think that the death was caused by the anaesthetic; then the coroner had to consider whether death by the anaesthetic administered in the ordinary and proper course of medical and surgical practice was an unnatural death within the meaning of the statute. It seemed to him that it was really difficult to say what was an unnatural death. If death by chloroform was an unnatural death—and, therefore, if the coroner had reason to think that the death was a death by chloroform, he must hold an inquest—it seemed to the President to follow that, if the death was caused by an operation, that plainly would be an unnatural death, and there would be an inquest in every case in which a man died from an operation. The two things seemed to be on the same footing. The resolutions proposed by Dr. Hewitt were carried.

A Bill to regulate the administration of general anaesthetics, the text of which was published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of December 5th, p. 302, was submitted by the Privy Council to the General Medical Council. Its two chief provisions may be summarized as follows:—(1) That no one but a registered medical practitioner should administer, or cause to be administered, any drug or substance with the object of producing unconsciousness during any medical or surgical operation, act or procedure, or during childbirth under a penalty not exceeding £10, and, in the case of a second or subsequent conviction, to a penalty not exceeding £20, unless the person was acting under the immediate direction and supervision of a legally-qualified medical practitioner, or if he had reasonable grounds for believing that delay in obtaining the services of a qualified medical practitioner would have endangered life. (2) That all examining bodies recognized by the General Medical Council should require that all candidates for final examinations should have received thorough instruction in anaesthetics, and should have personally administered anaesthetics under the supervision of their teachers.

The General Medical Council at its meeting last November approved the principle embodied in the first clause, but objection was expressed to the second on the grounds that it would override the functions of the Council, that the existing machinery was more effective, and that absence of a penalty would render the clause practically valueless. It was resolved that the Council should communicate with all the licensing bodies asking what steps

¹ Vol. v. Baillière, Tindall, and Cox, London, 1908. See also BRITISH MEDICAL JOURNAL, 1908, vol. i, p. 747.

they had taken to give effect to the recommendation of the Council of May 30th, 1907, that students should be required to produce evidence of having received practical instruction in the administration of anaesthetics. The reply of the Royal College of Surgeons of England to this circular was published in the *BRITISH MEDICAL JOURNAL* of December 26th, 1908, p. 1901. It was to the effect that the desirability of making instruction in the administration of anaesthetics a compulsory part of the medical curriculum was recognized by the Council of the College in 1901, and that in December of that year, in conjunction with the Royal College of Physicians, a regulation was adopted requiring any candidate before admission to the final examination to produce a certificate "of having received, at a recognized medical school and hospital, instruction in the administration of anaesthetics to the satisfaction of his teachers." It was added that questions on the subject are from time to time put to candidates by the examiners of the College.

In reply to a question by Mr. Bramsdon, the Home Secretary stated on December 14th that the General Medical Council did not see its way to support legislation to make practical training in the use of anaesthetics a compulsory part of medical education, but it was communicating with the various licensing bodies as to how far they have given effect to the Council's recommendations on the subject. On December 17th Mr. Bramsdon further asked the Home Secretary whether he would endeavour to obtain by means of an additional column in the next Coroners' Annual Return, the number of cases of death from anaesthesia upon which inquests have been held throughout the country, and whether he would further endeavour to obtain the number of deaths from the same cause reported to coroners in respect of which no inquests had been held. Mr. Gladstone replied that the forms for the next return had already been issued, but he said he would consider whether a special return can be called for. There the matter remains at present. We think, however, that a case has been made out for a comprehensive inquiry into the whole subject by a body competent to deal with it from every aspect, and trained to sift facts and weigh evidence. For this purpose it should include anaesthetists, general physicians and surgeons, coroners and lawyers.

Medical News.

UNDER the will of the late Mr. John Hodgson of Blackpool, the Victoria Hospital in that town and the Foxton Dispensary receive respectively £1,000 and £200.

AT a meeting of the Society for the Study of Inebriety to be held at 11, Chandos Street, London, W., on Tuesday, January 12th, at 4 p.m., Professor Arthur R. Cushman, F.R.S., will open a discussion on the action of alcohol.

THE King has been pleased to approve the appointment of Mr. H. H. Clutton, F.R.C.S., to the consulting staff of the Convalescent Home for Officers of His Majesty's Navy and Army, Osborne, Isle of Wight, as from Dec. 23rd, 1908.

AT the meeting of the Society of Chemical Industry at Burlington House, Piccadilly, W., on Monday next, at 8 p.m., Drs. S. B. Schryver and R. Lessing will read a paper on a physico-chemical method for comparing the antiseptic value of disinfectants.

DR. DUNDAS GRANT was recently presented by the amateur orchestra, which now numbers upwards of sixty members, including many members of the medical profession, of which he is the founder, with a conductor's desk. At the same time a silver rose-bowl was presented to Mrs. Dundas Grant.

AT a meeting of the Nottingham Medico-Chirurgical Society in December a resolution was passed expressive of its appreciation of the public services rendered by Dr. F. R. Mutch, who has long been an Alderman of the city of Nottingham, and recently laid down the office of Chairman of the Health Committee, after filling it with marked success for some eight or nine years. At one time Dr. Mutch was President of the Midland Branch of the British Medical Association.

THE St. Pancras School for Mothers, after a brief closure, reopened its doors on December 16th, 1908, at 37, Charlton Street, Somers Town. Little more than eighteen months have passed since this enterprise, with the assistance of Dr. Sykes, was started as a kind of *goutte de lait*, but the rapid success of the work and its growth in hardly anticipated directions necessitated the provision of roomier

quarters. It is now a centre for health work of all characters, but the prenatal and postnatal care of the child is still its main object.

SOME important additions to the Macclesfield Isolation Hospital were declared open on December 9th, 1908, a feature of the proceedings being a distribution to those present of an account of all the work in connexion with isolation at Macclesfield since the year 1873. This had been drawn up by the present medical officer of health, Dr. J. H. Marsh, and in a series of paragraphs, each covering a period of two or three years, recorded everything done in this connexion by Dr. Marsh's predecessors in office and himself. As it stands the account throws an interesting light on the work which active medical officers of health have to perform, and the difficulties with which they may have to contend. The end of the story is that the locality now has at its command a building capable of accommodating fifty beds (including twelve for patients suffering from small-pox) and thoroughly equipped for its work in every respect. Dr. Marsh is to be congratulated on his successful completion of the task, and on the fact that the value alike of the possession of adequate means for dealing with infectious diseases, and of his own services, seems to be freely recognized in the area in which he works.

THE yearly report of the National Sanitary Department of the Cuban Republic is practically a summary of the monthly *Informe Mensual*, but it is a model of what such a publication should be, and indeed there can be few documents of this nature with a greater elaboration of statistics. The past year is of importance in the annals of the island as the first in which all the sanitary services passed into the exclusive control of the National Board of Health instead of being in large part under local management, and consequently inadequately equipped and trained. Had the National organization been in force at the time of the outbreak of yellow fever in Cienfuegos in August last, it is probable that the disease would have been more quickly mastered. Altogether, during the year, there were 168 cases of yellow fever in the island, of which 56 proved fatal, but only 6 cases occurred in Havana. For the statistician there are some points of interest in the report. Both in the case of white and coloured parents there is always, curiously enough, a marked preponderance of male over female children among legitimate births, while in illegitimate births there is a preponderance of female over male in the coloured people, persistent throughout the years apparently, and in the whites, though not an actual preponderance of females, a much lessened proportion of males, the numbers being nearly equal—34,810 males to 33,927 females. But it is noteworthy that in the statistics of the sex of stillborn children (it is to be regretted that no record of this nature is kept in England) there is a large preponderance of males—337, as against 240 females. The total mortality has increased during the past year, rising from slightly over 30,000 to 34,000; the annual death-rate being 16.99, which cannot be said to be high. The least healthy months were June and July, with 3,620 and 3,920 deaths respectively; the most healthy November and December, with 2,142 and 2,228.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on December 18th, 1908; Dr. de Havilland Hall in the chair. The accounts presented showed that the growth of the society was still satisfactory, the number of new entrants during the year being exceptionally large. The question of the investment of the large funds of the society once more occupied the attention of the committee, and it was resolved that the plan hitherto adopted of keeping one-half on liquid—that is, Stock Exchange—securities, and the other half in advances to local bodies and other similar more permanent forms of investment, should be continued. The forthcoming valuation of the business was discussed, and it was resolved that the calculations should be made upon the same tables of mortality and sickness experience and at the same rates of interest as on previous occasions. The sickness experienced during the autumn of 1908 has been exceptionally light; but several additions have been made to the list of chronic cases—that is, of members who are not likely ever to be able to resume professional work, and will accordingly in all probability draw the society's half pay, usually 104 guineas a year, until the limiting age of 65. This is a risk almost peculiar to the business of this society, and at each valuation a substantial special reserve is made in respect of it. Prospectuses and all further particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, W.C.

British Medical Journal.

SATURDAY, JANUARY 2ND, 1909.

THE MEDICAL ASPECTS OF THE PARLIAMENTARY SESSION.

THE session of 1908 was a long and a broken one. It was interrupted early in its course by the death of the Prime Minister, Sir Henry Campbell-Bannerman, and afterwards by the adjournment in August for the holidays before an autumn session, which lasted from the middle of October till Christmas week. The first period witnessed the announcement of eleven measures in the King's speech, of which four have been passed, two have been killed in the Upper House, three have been withdrawn (two of which will be introduced again next session), one has been dropped, while only one of the eleven failed to see the light.

But this record by no means accurately expresses the work of what, after all, was a very strenuous and productive session. Altogether seventy-three Acts of Parliament have been passed, and of these fifty-four were Government measures, sixteen were enacted on the motion of private members, and three were Departmental Acts, for which the Government was responsible. No mere array of figures can, however, give any idea of the real importance of the Parliamentary proceedings of the last twelve months. Social issues of the most far-reaching importance have been raised, and in some instances settled for the time on satisfactory lines.

The second period, which saw the accession of Mr. Asquith to power, was remarkable, and always will be remarkable, for the passing of the Old Age Pensions Act as part of the Budget. The third period of the session will be remembered for the rejection of the Licensing Bill by the Lords and the enactment of the Children Act and the Coal Mines (Eight Hours) Act, two measures of wide social and economic significance. The medical aspects of this kind of legislation do not obtrude themselves on the surface, but are nevertheless important. Old age pensions, which were first prominently advocated on political platforms by a medical member of Parliament, naturally commend themselves to a humane profession, as affording honourable support for the deserving poor in extreme old age. It was with this object they were first suggested, and in spite of the defects of the Act as passed, this object will be largely attained. But, as has been previously pointed out in the *BRITISH MEDICAL JOURNAL*, the grant of these pensions to some half a million old people will have a direct bearing on medical practice by throwing a considerable amount of work on Poor-law medical officers. Many thousands of aged persons who are now treated in workhouse hospitals, will in future require medical attention in their own homes, and as medical relief will not disqualify for the receipt of the pension, the parochial medical officer, in whatever form the Poor-law Commission may leave him in existence, will find plenty of work among the State pensioners of the future. We dwell on this point in no spirit of complaint, but rather to show how closely

and inextricably nearly all social reforms are woven into the woof of medical work. A year or two back we were discussing and legislating for the feeding of half-starved children in elementary schools. It was only vaguely recognized as a medical question; but now we see all over England medical inspection of the children at school and a new class of medical appointments created, of great sanitary and scientific promise. Many similar illustrations might be given to show how even more and more closely social reforms must affect the profession of medicine.

The Children Act, which consolidates and extends State control as respects the life and health of children, will always honourably distinguish the Parliamentary output of 1908. Under it baby farming, which years ago this *JOURNAL* did much to reform, will be regulated, checked, and more adequately supervised. Vagrancy in its most pernicious forms as regards child life will be reformed, and the establishment of Children's Courts will rescue youthful offenders from association with criminals. The Prevention of Crime Act will also help in this direction by extending the reformatory system. Under the Children Act, too, the juvenile smoker will be frightened, if not suppressed, and a habit specially injurious to the young frowned on with State authority. We hope for much good from this Act as regards the humane, moral, and hygienic management of child life, and much from its educational influence in forming public opinion. Infant mortality and national degeneracy have long demanded such legislation.

The Act which restricts the labour of coal miners to eight hours' work underground is one which has always appealed to some medical thinkers on the general grounds which seek to limit long hours of physical toil, especially as regards the young and growing lads employed in the pits. It is the good of this latter class of coal workers which has always afforded the strongest argument for the measure.

The Irish Universities Act, which is one of the principal measures of the session, will, we hope, promote higher education in Ireland. There are some fears that it may adversely affect an existing medical school in Dublin, but we hope these fears will prove groundless. Should they not do so, it will certainly be the duty of the Government (and we think they admit this) to protect the interests of the College of Surgeons in its school out of common gratitude for the excellent work it has done for so many years.

In the Tuberculosis Prevention (Ireland) Act we have an experiment in legislation which may, if carefully and sympathetically administered, help to check the ravages of tubercle among the Irish people. There is a large field for useful work, there is lofty enthusiasm in high quarters for the crusade, and we hope every local authority will rise to the occasion and co-operate to work an Act that promises much to lessen human suffering and to save thousands of lives in a dwindling population. A recent Local Government Board order in England shows that the notification of tuberculosis is on the way to become law here, too, and that the State, if somewhat tardily and vaguely, is beginning to recognize its duty in stamping out preventable diseases.

The Act which forbids after next year the use of white phosphorus in the manufacture of matches, is another example of action of this kind, and is creditable to the Home Office. We may now look forward to the extinction of phossy jaw, and congratulate this country on at last placing itself in line with the other

nations which have prohibited since 1906 by the Berne Convention the manufacture and sale of matches made of this substance.

Lastly must be mentioned two great measures which failed to pass. The Licensing Bill had naturally a host of enemies, for it touched the most sacred of all political interests—property. This was fatal to it. All medical men are agreed that the repression of intemperance is an urgent problem, but there may be legitimate differences of opinion as to the manner in which the Government proposed to deal with it. The other measure that did not become law is the Housing and Town Planning Bill. In Committee, after many weeks of hard work it had been much improved, and would have made a workable, if not an ideal, Act. We are promised that it shall be brought up again next year, and we hope to welcome it then even in a better form than it left the Committee this last session. We trust that the improved position of medical officers of health will be still further extended and secured, and we think if the town-planning clauses were made into a separate bill that both housing and town planning would be more effectually promoted.

This cursory glance at the last session cannot close without the reflection that medical men as a class are deeply interested in watching legislation. They are the only men in daily touch with the health of the people, and know more than any other class how closely morality and well-being are bound up with the physical surroundings that influence health. Experience teaches daily how legislation, apparently remote, affects the doctor in his daily work and often touches his interests. As the progress of social reform advances this must become increasingly true, and Parliament, however unwilling, will have more and more to listen to medical counsel and guidance.

THE CAMPAIGN AGAINST TUBERCULOSIS IN BELGIUM.

THE annual report of the Belgian National League against Tuberculosis presents, in the evidence it affords of the organized enthusiasm displayed and the work actually accomplished, a striking contrast to the indifference shown by the public generally in this country. The Ligue Nationale Belge contre la Tuberculose was instituted in 1897 under the patronage and with the co-operation of the Société Royale de Médecine Publique et de Topographie Médicale de Belgique. Its object is to combat human tuberculosis by every means, but especially by disseminating information through the press and by lectures, by studying the preventive measures which should be adopted by public bodies, philanthropic associations, and private persons, and by the establishment of sanatoriums for the poorer classes.

The league is composed of persons of any rank or profession who are willing to join it, and of members of the Société Royale de Médecine Publique. It has as many sections as there are provinces. There is a general committee of thirty-seven members, upon which each province is represented, and an executive committee of eleven chosen from the general committee. The funds are derived from annual subscriptions, private donations, and grants from public bodies. The sections contribute in proportion to their receipts. The central office is maintained partly by an annual grant from the Société Royale de Médecine Publique and partly by a percentage paid by branches,

and partly by gifts, subsidies, and other money contributed for the general purposes of the scheme.

The principal feature is the dispensary, which, where possible, works with the sanatorium or hospital, but at present there are more dispensaries than sanatoriums. The dispensary is careful not to trench upon the practitioners' domain, and it is made clear that patients are merely examined from time to time, given general advice, and, when necessary, practical assistance. It seems strange to read that, in spite of this, few doctors take advantage of the opportunities afforded by these institutions, at once scientific and charitable, where, besides valuable hygienic advice and literature, material assistance is given to deserving cases. Thus, milk, eggs, meat, and pocket spittoons are distributed, while suitable cases are sent to sanatoriums, the cost being defrayed by the mutual societies or by philanthropic individuals. When the enormous loss to the family of the working man thrown out of work is taken into consideration, the practical value of such assistance is obvious. The doctor of the dispensary visits from time to time the patient he sends to the sanatorium, notes the progress made, and endeavours to keep in touch with him after he leaves. Many, after a few months, resume their ordinary work, and appear to keep well. There is a tendency, however, on the part of the tuberculous to neglect themselves until the disease is far advanced and recovery improbable. Great difficulties are encountered in inducing them to realize the danger they are to other people, and it is found that patients in the most highly infectious state share rooms and even beds with their families, never dreaming that they are doing wrong. It is difficult to persuade them to move into a separate room, even though the dispensary pays for the rent and furnishing. There is not the same reluctance to go to a sanatorium.

One of the most interesting aspects of the work is to be noted in Antwerp, where the energies of the section are chiefly devoted to prophylaxis in childhood. The Villa Maritime pour Enfants Débiles at Wenduine was established five years ago for delicate children born of tuberculous parents, for rickety, strumous, and lymphatic children, and for those suffering from internal tuberculosis. Here children are received from all over Belgium, and the results are admirable. The Hainaut section reports that, of 75 cases received during 1907 at the Galerie de Cure d'Air de Bois d'Havré, maintained by the four dispensaries of Mons, Tournai, Charleroi, and Ath, 45 per cent. were discharged cured and able to work whole time after an average stay of five months.

The movement, taken broadly, has three aims: Prophylaxis in childhood, the most vitally important of all; the education and possible cure of grown-up patients by means of the dispensary and the sanatorium; the isolation, in their own homes, of far advanced cases, who in the ordinary course of events may do much harm in spreading the disease. These last go probably in the first instance to the dispensary, and because, owing to the advanced stage of the disease, the dispensary cannot conscientiously send them, with any hope of recovery, to a sanatorium, they resent and grow tired of advice, and become enemies of the movement. They are not reasonable enough to blame themselves for coming too late. Up to the present nothing practical has been done for women, but as a sanatorium for them is about to be opened, they also will have their chance. More might be done for children, but, seeing that we in this country have done little or nothing for them,

we are not in a position to criticize a nation which has at any rate made a beginning.

Dr. Lentz, director of the Hainaut dispensaries, gives some interesting information as to the class of patients visiting these institutions: the rule was that no patient should under any circumstances be received at the dispensaries unless he could produce a certificate of his indigence. After careful observation, Dr. Lentz thinks this a mistake, inasmuch as it shuts out a large class of the population fairly comfortably off, but quite as much in need of advice and hygienic education as the poorer classes. The dispensary is unable, for financial reasons, to distribute relief continuously, and many of those patients who are assisted only attend during the months when such relief is being given; the most constant and conscientious are to be found amongst those who do not receive help, because they go voluntarily to the dispensary for advice and not from any ulterior motive. The material help given was greatly reduced with the unexpected result that after a few months a special class of patients began to attend. At first, owing to the rules of the dispensary, they were sent away, only to return armed with letters from their doctors, and begging for instruction in prophylaxis. These patients included the better-class workman, shopkeepers, and even the middle classes, who so long as the dispensary was limited to the necessitous poor considered it a loss of dignity to attend. In this accidental way was brought to light a class usually neglected because neither rich enough nor poor enough to receive special notice.

Perhaps in the present stage of ignorance of the subject by the general public the most far-reaching good is done through the press. In the Namur section alone Dr. Lefèvre has secured the co-operation of sixty-five papers, in which he deals from time to time with the history of the disease and the league's plan of campaign.

This great work might well be imitated in England where unfortunately we seem to have no general plan of campaign; hence the majority of our population are painfully ignorant of the theory and history of a disease which might be wiped out if each of us co-operated intelligently and conscientiously.

THE ANTHROPOLOGY OF SCOTLAND.

In an article published in these columns in 1907,¹ attention was directed to Mr. J. F. Tocher's valuable work on the anthropometric characters of the Scottish insane. The same worker has recently completed an important study of the pigmentation characters exhibited by the normal school children of Scotland.²

The survey was organized by a committee consisting of Sir William Turner, Professor R. W. Reid, Mr. J. Gray, and Mr. J. F. Tocher, and the expenses of the work were partly defrayed by grants from the Royal Society and the Carnegie Trust. Thanks to the care with which the details of the investigation were planned and the loyal co-operation of teachers, complete returns were furnished from 2,288 schools, containing the records of ages, sex, fraternal and cousin relationships, and colour characters of 257,766 boys and 244,389 girls.

Taking first the question of hair colour, it appears that about one-fourth of the children are fair haired, one-fourth dark haired, and the rest fall into two intermediate classes comprising the various shades of brown or medium and red hair. About 5 per cent. of the population have red hair. The distribution is markedly different from that of certain foreign countries in which a similar survey has been effected. In Prussia 72 per cent. of the children are fair haired, in Saxony 69 per cent. Even in South Germany the proportion is larger than in Scotland, Baden giving 58 per cent., Württemberg 62, and Bavaria 54. In Scotland 22 per cent. of the children have dark brown or dark eyes, and over three-fourths blue, light, or medium. About 15 per cent. possess pure blue eyes, 30 per cent. light eyes, and 32 per cent. the varieties classed as medium. Germany as a whole has significantly more dark eyes than Scotland—32 against 22 per cent.

The pigmentary distribution is by no means uniform; thus, excess of fair hair and blue eyes occurs for the most part in North Scotland, including Orkney, Shetland, the Isle of Lewis, Ross, Cromarty, Elgin, Nairn, and Perth, with parts of Stirling, Forfar, and Fife.

It was found that regions of excess of dark haired, jet black haired, and blue-eyed classes are associated with regions of excess in Gaelic-speaking population. The correlation coefficients for dark hair and blue eyes with the percentage of Gaelic-speaking persons are 0.8126 and 0.8563 each, being more than three times the size of its "probable error" (for the particular case $r=0$). Although the effect of foreign immigration upon the characters of densely populated areas is demonstrated, it is pointed out that "neither the Highland, Irish, English, nor foreign elements in the population account for the high proportion of medium hair found in all densely populated regions. These elements, however (excepting the English), where present, tend to increase the proportion of dark and jet black hair." Mr. Tocher holds that the excess of medium hair in populous districts is probably due to the blending of colour in the offspring of fair and dark haired persons, a hypothesis which finds further support in the fact that, as a rule, medium hair is not associated geographically with any other tint.

It is shown that definitely more cases of imbecility, blindness, and deafness occur in Gaelic-speaking districts than throughout the rest of Scotland, which may be due to a greater rate of emigration from and relatively little immigration to the Highlands on the part of fitter stocks.

The special characters of the Glasgow population are discussed in detail and many factors are seen to be involved.

The degree of association between eye and hair colour deduced from these results agrees well with values already obtained from other British and foreign data. In a summary of some of the more interesting features, it is impossible to do justice to the admirable patience and accuracy which have been brought to bear by Mr. Tocher on the completion of his laborious task. It would not be true to say either that the memoir is very simple to read or that it is easy to avoid being confused by the wealth of details. We doubt, however, whether the reader's path could have been made smoother, and we congratulate both Mr. Tocher and his committee on an important contribution to anthropological literature.

¹ BRITISH MEDICAL JOURNAL, 1907, vol. i, p. 1204.

² *Biometrika*, vol. vi (1908), pp. 150-235. (The complete data are published as an appendix to this part of *Biometrika*.) An account of Mr. John Gray's *Memoir on the Pigmentation Survey of Scotland*, published by the Royal Institute of Great Britain and Ireland, was given in the *JOURNAL* of July 25th, 1908, p. 212.

SHOCK AND ANAESTHESIA.

MR. STEPHEN COLERIDGE has for once done a useful thing. He sent a circular letter to the Vice-Presidents of the Research Defence Society misrepresenting in the manner familiar to our readers the evidence given by Dr. Dudley Buxton before the Royal Commission on Vivisection in regard to Dr. Crile's experiments on surgical shock, and insinuating that anaesthetics are not adequately given to the animals upon which experiments involving surgical operations are performed. He rings the changes on the expressions "light anaesthesia," "incomplete anaesthesia," etc., as used by experimenters, with the view of leading people ignorant of the subject to believe that they imply a condition of partial sensibility to pain on the part of the animal. We have given a full abstract of Mr. Coleridge's evidence before the Royal Commission on Vivisection.¹ In that evidence he furnished ample proof that the technical meaning of "incomplete anaesthesia" had been fully explained to him, and he admitted he had been told that the Home Secretary had caused investigation to be made into these experiments, and that the information received from competent persons, who either witnessed most of the experiments or had read the account of them, was to the effect that in no instance had the animals experimented upon been subjected to pain. Mr. Coleridge refused to accept the statement, amiably remarking that his point was that when experimenters said that "slight anaesthesia" covered absence of pain, they said it to cover themselves from the Act of Parliament. In other words, his point is that all experimenters lie and break the law in the same light-hearted manner in which he gave the Commissioners the impression that he himself habitually violates the Motor Car Act. Mr. Coleridge's circular has had the effect of drawing a letter from Sir Victor Horsley, published in the *Times* of December 30th, which contains a statement on the subject of Dr. Crile's experiments, divested of all technicalities, which places the matter in a light that the most tortuous sophistry cannot obscure. After explaining that, as the experimental researches of Pasteur and Lister had removed the commonest cause of suffering and death after operations—namely, blood poisoning—there remained practically only one equally serious and general risk—that of shock—Sir Victor points out that it has become a paramount duty on the part of those to whom human lives are entrusted to endeavour to understand the causes underlying that risk. For the utility of any experiment designed for this purpose it is obviously necessary that a reproduction of the methods employed in ordinary surgical operations on human beings should be secured. He accordingly arranged in 1895 with Dr. Crile that he, following the usual operation routine in the administration of the anaesthetic, the nature of the incisions, the dividing or crushing of bone, the exposing and handling of the nerves or organs of the body, should begin by investigating the effect of such procedures on the circulation and respiration of the animals experimented upon. In pursuance of this scheme, each of the animals was anaesthetized throughout, just as in a regular operation, commencing with a massive dose, producing absolute unconsciousness, with an almost complete abolition of reflexes, followed by a diminution of the anaesthetic, which, while securing a continuance of the insensibility to

pain, permits a return of certain reflexes. This is the condition which Dr. Crile termed "incomplete anaesthesia" and Dr. Buxton "light anaesthesia." The wording of these terms is nothing, the technical meaning being the same, namely, that the person, or in this case the animal, operated upon was insensible to pain. Sir Victor Horsley adds that on the completion of each experiment and before recovery from the anaesthetic the animal was killed by an overdose, and thus, from the first moment of the operation to the last was unconscious. Had, he goes on to say, Dr. Crile performed the experiments in the way Mr. Coleridge suggests, the whole purpose of the research would have been frustrated, and not only would the law have been broken, but the experimenter would have also shown himself incapable of performing his task. Sir Victor Horsley concludes as follows: "In view of all these facts, which have been perfectly well known to Mr. Coleridge for about ten years, and have often been published in the press, as well as during the past year before the Royal Commission, it appears to me unnecessary to say more." We cannot help congratulating Mr. Coleridge on having been the means, however involuntary, of bringing before the public this clear exposition of a subject as to which there has been much misconception.

PROPRIETARY CURE-ALLS.

IN the report on the composition of some secret remedies which we publish this week particulars are given of the results of the analysis of a few of those nostrums for which the most general and varied curative powers are claimed. The exposures of quack medicines which we have already made have shown that the most extravagant and ridiculous pretensions are advertised by the proprietors of some of these preparations belonging to practically every one of the classes dealt with; it is natural, therefore, to expect that among those for which the most general claims are made such pretensions will not be lacking. The particulars quoted show that the expectation will be fulfilled. Thus, one of the articles described is stated to cure such different disorders as constipation, rheumatism, St. Vitus's dance, heart disease, rickets, sleeplessness, kidney complaints, and women's special ailments, among many others, and is said to be "a real elixir of life in solid form"; the facts as to its composition, ascertained by analysis, show what the possibility of its being a "cure" for heart disease, for instance—is. Another of the nostrums dealt with this week is the "Pink Pills," advertisements of which are to be found in almost every daily and weekly paper. The method followed appears to be to recommend them for different diseases in different advertisements; personal testimony, or what is put forward as such, from sufferers who have been "cured" is made the basis of most of these, and illustrations are employed to catch the eye of the casual reader. Our analyst's report shows that these pills are practically the ordinary Bland's pill, though of lower strength than usually prescribed, and to judge by the proportion of iron that was found to be in the higher state of oxidation, very carelessly prepared. They differ vastly, however, from other Bland's pills in the price charged for them. Thus the proprietary Pink Pills are sold at a little over a penny each, while coated Bland's pills can be bought retail at a few pence a gross, and wholesale in large quantities at a little over a penny a gross. Other analyses show the same disparity between the price of the drug supplied and the price charged to the person who is beguiled into purchasing; thus thirteence-halfpenny, two shillings and sixpence, and two shillings

¹ BRITISH MEDICAL JOURNAL, January 4th, 1908, p. 31; January 11th, p. 90; January 18th, p. 155; January 25th, p. 209; February 1st, p. 266; February 8th, p. 333; February 15th, p. 335; February 22nd, p. 455.

and ninepence are the selling prices of nostrums the ingredients of which are estimated to cost respectively one-eighth, one-third, and one-tenth of a penny.

THE CANCER PROBLEM.

SEVERAL times during the last few years proposals have been made from various quarters that an international congress should be held to discuss the cancer question. When the inaugural meeting of the International Cancer Research Association was held in Berlin in the spring of 1903 a proposal was made—*officiusement*, to speak the language of diplomacy—that the first meeting of the congress should be held in London. The same proposal was again brought forward in a more definite form at the International Congress of Surgery held at Brussels last September, the year 1910 being suggested as the date. We understand that the matter was discussed at a recent meeting of the Executive Committee of the Imperial Cancer Research Fund, but the committee did not see its way to agree to the proposal, as it was felt that the time was not yet ripe for such a congress. We think this feeling will be shared by many of those who have been working hard at the cancer problem in recent years. The question is still in too inchoate a state to justify the assembly of an international congress for its discussion. This is shown by the fact that congresses on cancer held elsewhere have not been particularly fruitful of results. What is wanted at present is a concentration of effort and a co-ordination of research. Our own workers do all in their power to encourage international collaboration and give freely both of the knowledge they gain and of the materials on which it is based. But it is too plain that there is division of energies elsewhere. Quite recently, we learn from the *Berliner Tageblatt*, a meeting was held in Berlin to discuss a proposal made by Professor von Leyden to raise funds to establish a cancer hospital. Among those present were Herr von Moltke, the Minister of the Interior, Professor Kirchner, representing the Cultusminister, Professor Orth, Professor Reuvers, the Kaiser's Chamberlain, the President of the Berlin Red Cross Society, Professors Hansemann, Georg Meyer, and Lazarus, the Treasurer of the German Central Cancer Research Committee, and several well-known financiers. Professor von Leyden having pointed out that other countries had already large hospitals for cancer, and that Berlin was behind in this respect, went on to state that within certain limits cancer could be cured by medicinal treatment. He himself had obtained good results in a few cases, though the lapse of several years was required to establish proof of cure. He dwelt also on the danger of infection, which made isolation necessary, and urged the formation of a committee. Professor Kirchner, speaking in the name of the Cultusminister, said the proposal needed serious consideration; to be frank, he said, research has at present not gone very far. Professor Orth was still more sceptical; the formation of a new committee, he said, would look like a vote of a want of confidence in the old. It would be possible only in the form of a subcommittee. He was also opposed to the whole idea of building a hospital for the internal treatment of cancer. So far, the only effective treatment was the knife. It would be better to continue the work of research. In reply, Professor von Leyden said that in his small cancer institution, where he treated from ten to fifteen patients, there were at least a few cases of improvement. He remembered the time when the possibility of a cure for tuberculosis was denied. Professor Lazarus said that

there had been an enormous increase of cancer; in Prussia 1 out of every 1,500 persons fell a victim to the disease; in Berlin the number had risen in ten years by 4 per cent.; at present only 10 per cent. were cured, and that was by operation. If a cancer hospital was to be founded in Berlin, it should be for the treatment of the disease by operation as well as by medicinal substances. The Minister of the Interior opposed the establishment of a new independent committee; he agreed with Professor Orth that it should be connected with the existing committee. Professor v. Hansemann, speaking of the increase of cancer, said that it could now be recognized whereas formerly it could not. He disapproved of the establishment of a special hospital on the ground of humanity; every sufferer from cancer would think himself doomed when taken to the hospital. He affirmed that hitherto a cure had not been obtained by medicinal methods. In a second speech Professor Orth proposed that an institute for the investigation and treatment of cancer should be founded. This proposal was agreed to. It was also decided to form a committee in connexion with the Central Cancer Research Committee for the purpose of raising funds for existing cancer institutes and establishing others. This, we suppose, was by way of making a bridge for Professor von Leyden to get out of an untenable position. By all means let treatment of any kind that offers a reasonable hope of success be tried, so long as the patient's prospects of recovery by the aid of surgery are not imperilled. But let all co-operate to the attainment of a common end, that is, the discovery of a means of preventing or curing the disease which is most dreaded by the majority of mankind and which hitherto has defied all endeavours to find a certain remedy. Division of effort is obstructive to progress and confusing to the public, which would contribute more abundantly if the goal was more plainly in view.

THE RETURNS OF THE GERMAN SICKNESS INSURANCES.

IN discussing the returns of the German sickness insurance for the year 1906, Dr. A. Fischer¹ makes some extremely interesting observations. The total population of Germany is somewhere about 61 millions. Of this number, 11,700,000—that is, 19 per cent.—are insured against sickness. This percentage is the highest existing. In Austria only 10 per cent. of the population is so insured. The German sickness insurances are worked on several systems. Of these the most important are (1) the Municipal (*Gemeinde*), (2) the Local (*Orts*-), and (3) the Works (*Betriebs-Krankenkassen*) insurance societies. The last named are the most active. The municipal insurances do the least for the insured; the works societies do the most for the workmen, but objection is taken to these organizations at times, as the employers are largely responsible for the management. The local societies do not support their insured quite so well. In 1906 the municipal clubs paid out as sick pay per member M. 11.28; the local clubs paid out M. 20.50; while the works clubs paid out M. 26.30. It may be pointed out that the law has fixed a minimum in respect to the sick pay which the insured has a right to claim.² Not infrequently the societies pay in excess of this minimum. The contributions for the insurance against sickness vary between 1 and 1½ per cent. of the daily wages of the labourers in the municipal societies, and between 2 and 3 per cent. of the average daily wages of the special class of workman in the works' societies. The local societies fix their contributions according to the benefits allowed, but the scales com-

¹ *Muench. med. Woch.*, November 10th, 1908.

² *BRITISH MEDICAL JOURNAL*, June 20th, 1908, pp. 1523-1524.

pare well with the other two. The first-named societies do not pay for funeral expenses, for confinements, or for the support of the families of sick workmen. After discussing the comparative membership of the three classes in the various parts of the German Empire, he turns his attention to the question of confinement allowances. During the year the expenditure under this head was nearly 5 million marks. The total amount expended by the sickness insurances was 104 million marks. Dr. Fischer compares the sums with those paid by the Hearts of Oak in England, which he puts at £360,000 for sickness and £44,000 for confinement allowances. The municipal societies have no provision for confinements, although this class of sickness insurance caters for a larger percentage of women as compared to men than either of the two other classes. In 1905, to every 100 men insured against sickness, 33.9 women were so insured. In the municipal insurances there were 51.5, in the local insurances there were 39.7, and in the works' societies there were 25.7 women to each 100 men. Dr. Fischer considers that, in view of this state of things, private enterprise should come to the assistance of women and a private "young mothers'" insurance should be instituted. A similar movement exists in France under the name of the *mutualité maternelle*.

DISTURBANCES IN THE PARIS MEDICAL SCHOOL.

OUR Paris correspondent gives an account of certain disturbances which have recently taken place in the Paris Medical School, partly by way of demonstration against an unpopular professor, and partly by way of protest against a new examination which has lately been instituted. Professor Bouchard, President of the Board of Examiners, called in the police, and the Chief of Police in turn called in the Republican Guard. A good many heads were broken, but the examination was reduced to a farce, and the Faculty has closed its dissecting-rooms to first and second year students till March 1st. Professor Osler, who was an eye-witness, gives a clear account of the last and most serious of the disturbances. This occurred on December 21st. Those who took part in it, he says, were not students, "but men comparable in years and repute with the assistant physicians of the London hospitals or with the younger Oxford tutors—men of from 30 to 35 years of age, many of them with European reputations. The examination was the *concours* for *agrégation*, that is, for the *agrégé* professorships "for twenty places in all the branches in all the medical schools of France. There were 128 candidates. A new regulation had come into force by which this was to be a preliminary *concours* of admissibility, an examination in elementary subjects—"anatomy and physiology." This has been most unpopular because, we may say parenthetically, it virtually amounts to the exclusion of all but men who can afford to leave their practices or their scientific work in distant places for some months in order to revise their early studies. Professor Osler says the senior men protested energetically against the invasion of the school precincts by the police. When the jury, or board of examiners, walked in headed by Professor Bouchard, they were greeted by a storm of protests. The examination was adjourned till December 24th and then only a small fraction of the candidates took any part in it. It was then adjourned *sine die*, but the incident is not yet closed. A deputation waited on M. Clemenceau, who gave it a sympathetic reception and expressed disapproval of the action of the police. The original *casus belli*, the new preliminary examination, is to be

considered by the Government. While regretting that the disturbances should have occurred, we feel bound to protest against some remarks in which the *Times* has thought fit to indulge on the subject. It says: "For some reason that seems to invite pathological inquiry, the medical man in his larval stage is peculiarly addicted to rowdiness. Students in other faculties, though exhibiting some youthful exuberance, give, upon the whole, satisfactory indications of the grave demeanour they are to assume in 'after-life.'" It goes on to ask if there is some subtle connexion between study of physiological disorders and sympathy with disorder in the body politic, and if the course of study inoculates a naturally mild and peaceable youth with the virus of insubordination? Our esteemed contemporary is half a century behind the times. Medical students of the present day are no more rowdy than other young men of high animal spirits; indeed, they compare favourably in this respect with the "men" of Oxford and Cambridge who find amusement in the senseless smashing of property and other diversions which bring them in contact with the vulgar policemen, of whose coarseness an Honourable and Reverend gentleman has recently so pathetically complained. They compare still more favourably with the young officers who find an outlet for their exuberant vitality in foolish and often cowardly "ragging." We are speaking for the British student. Professor Osler, who also protests against the charge of special rowdiness made against medical students by the *Times*, has a good word to say for those of Paris. He says that, as he has seen him during the past three months at work in the hospitals, the Paris medical student is a very hard-working fellow, keenly alive to the importance of scientific and practical medicine, and with a charming touch of human sympathy with the patients entrusted to his care. *Pace* his belated traducers in the *Times* and elsewhere, exactly the same thing may be said of the medical student of London and other schools in the United Kingdom.

COMPULSORY OPERATIONS AND THE COMPENSATION ACT.

THE vexed question whether a workman can be compelled to undergo an operation which will tend to increase his powers of working has recently been decided by the Court of Appeal. In the case which came before that tribunal it appeared that the claimant's foot was injured on February 18th, 1907. The foot was treated at a hospital, with the result that, after two or three small operations, the second toe and part of the big toe were removed. As the applicant still suffered some pain, a skiagram was taken which showed that a piece of bone, detached at the time of the accident, was loose in the stump of the big toe. Compensation had been paid at the rate of 14s. 10d. down to May 4th, 1908, when the applicant agreed to submit himself to an examination by his own doctor and the employer's doctor, and to do what they advised him. They advised a simple operation, but he refused to undergo it. The employers then went to the county court judge to have the compensation reduced. The judge found that the operation was simple and without risk; that the applicant had good health; and that it was doubtful if the applicant's toe would ever recover without an operation. He also found that the operation was one to which any man of ordinary nerve would submit in his own interest. As he felt bound by a previous decision of the English Court of Appeal, he felt that he could not reduce the compensation. The Court of Appeal, however, pointed out that in the case to which

the county court judge referred it had been expressly found that the operation which it was sought to make the workman undergo was attended with very considerable risk. After stating that the finding in the present case was quite different, the Master of the Rolls said: "Without saying that a man can be compelled to undergo an operation, I say that, in my opinion, if an operation is not performed, the continuance of the incapacity will be due, not to the original accident, but to the unreasonable conduct of the workman in refusing to submit to an operation." Lord Justice Moulton said: "If the respondent's case is right a man may have a wound, however small, and by refusing to have it dressed he may get a sloughing sore which will totally incapacitate him. It is not possible to draw the line between dressing and operation; the distinction to be drawn is between reasonableness and unreasonableness." In the event the case was sent back to the county court judge in order that he might review the compensation allowed to the workman. This is the first case in which the English Court of Appeal has virtually declared that a workman must undergo an operation. The Court of Session in Scotland had reduced an applicant's compensation where he had refused to undergo a simple operation, and the fact that the Court of Appeal has adopted the same principle ought to have a good effect. It would be difficult to imagine anything more prejudicial than the adoption by the courts of a hard and fast rule to the effect that partial disablement which might be cured by an operation should entitle an injured workman to compensation for the rest of his natural life.

THE ORGANIZATION OF CONGRESSES.

THE demand for reform in the organization of congresses is not new. Defects in organization lead to defects in working, and result in failure and dissatisfaction. For some years it has generally been recognized that this work should be in the hands of a central permanent committee. This is the only way in which the perpetuation of mistakes can be avoided, and to ensure that future congresses will be arranged on a workmanlike basis. The essential object of a congress is, of course, the furtherance of knowledge by discussion. To achieve this end competent persons should exercise a wise discretion as to what should be discussed and by whom the discussions should be opened. That this is by no means always done appears from the programmes. No useful purpose can be served by crowding the day with an unmanageable number of papers on various subjects. No furtherance of knowledge is gained by allowing a man to get up and to repeat what he said last year and the year before last. No benefit can be derived by personal controversies on the question of priority or by personal attacks on professional brethren. And yet such things are not uncommon at congresses. It is necessary on various grounds to make a selection among the communications offered. All this can only be done by careful consideration of experienced men, well versed in the subjects of the special congress. The modern congress is apt to miss the mark in another respect. It is often stated that one of the chief advantages of a congress is that it gives opportunities of making personal acquaintance with fellow workers who live at a considerable distance. It is therefore well to supply opportunities for the members of a congress to come together in private as well as in public. But this end is scarcely attained by the arranging of great and lavish feasts, by the securing of a gala performance at the opera or theatre, by organizing a bull fight or by other similar means. Dr. Mamlock¹ takes

a sensible view of this part of congress arrangements and shows in figures the cost of a variety of congresses. Within the last twenty-five years, the city of Berlin has spent nearly £14,000 on congresses. The highest figure mentioned is that of £3,555 for the meeting of the German scientists and physicians in 1886. Without going into minutiae with regard to the amounts spent in entertainment, *Festschriften*, and other forms of literature supplied gratuitously, it may be interesting to quote this author again with regard to the multiplication of congresses within recent years. He finds that in 1883 only seven were advertised in the *Deutsche medizinische Wochenschrift*, whereas last year the number had increased to forty-one. He maintains that the increase in number does not mean a corresponding increase in scientific importance, and quotes v. Graefe, who is said to have summarized a congress as follows: "I had a veritable 'next morning' feeling in my whole body: learned nothing, talked big, and only enjoyed room atmosphere and poisonous restaurant dinners." The remedy is not to be sought in the doing away with all social functions, which must be among the attractions of a congress. To limit the expense of the entertainments; to arrange for the publication of the proceedings on sound business lines; to make the members pay for their theatre tickets—all this does not mean to exclude all social intercourse, and admits of ample private exchange of views on science and other matters. The disclosure of this wanton extravagance, however, drives us to the conclusion that the ideal congress is still a long way off.

COWS AND TOOTHBRUSHES.

WE have often had to comment unfavourably on the nature of the announcements on medical subjects appearing in the lay press. As a rule, they are either calculated to make the "flesh creep," or to raise hopes that are impossible of fulfilment. In justice to the latest of such announcements it can be fairly claimed that, in spite of its title and theme, it is not likely to cause undue alarm in the public mind. In the chief page of the Christmas Day issue of the *Daily Telegraph*—no doubt inserted as a seasonable novelty for its readers—is a paragraph entitled "dangers of milk." It would seem that Dr. Tanner, of fasting fame, is now "preaching a health campaign at Los Angeles." We learn that "Dr. Tanner is convinced that bovine teeth harbour many germs hitherto unsuspected, and that these frequently contaminate children's milk, producing all kinds of complaints which his fellow practitioners have talked wisely about but do not in the least understand. He recommends that the teeth of all dairy cows should be cleaned twice daily, and says that this law should be compulsory." It is well that this important pronouncement should receive prominent notice and not be lost to the world. The doctor, who is evidently learned above his fellow practitioners, might have gone a step further and given some directions as to the method of carrying out this bovine dental toilet. Of a well-known character in Chaucer it is recorded, "He scrubbed his mouth with sope and eke with sand." But both soap and sand might possibly be objected to by the learned doctor on the ground that they might travel by the same route as the malevolent germ, and find their way into the milk. We would suggest in place of either of them the employment of the toothbrush. As in the case of the Scot with the ample nose regarding the use of snuff, the cows with their dental development would afford "gran' accommodation" for the implement proposed.

¹ *Deut. med. Woch.*, November 25th, 1908.

Again, as the germs are not likely to be restricted to the regions of the teeth, but would probably find a location in other parts of the mouth and pharynx, we would further suggest that each cow should be supplied with an antiseptic gargle as an addition to the toothbrush. Thus fully equipped for the encounter with the germs, we might feel regarding the cows, in the words of Mrs. Bangham on the arrival of Dr. Haggage at the impending accouchement of Mrs. Dorrie, "Now we are complete."

CAMBRIDGE WATER SUPPLY.

EXCEPT in a very few instances, where the supply is derived from wells, the inhabitants of the town of Cambridge obtain their water supply from the mains of the Cambridge University and Town Waterworks Company. The company's sources of supply are from a spring and from wells sunk in the Lower Chalk and through the Chalk and the Gault into the Lower Greensand. A considerable population resides in the neighbourhood of the sources of supply in Cherry Hinton and Fulbourn, where there are about 150 and 310 houses respectively. These two villages are about a mile and a half apart, and nearly midway between them is situated the county lunatic asylum. For several years past attention has been directed to the possibility of the pollution of the water supply, and more especially since the occurrence at the asylum of an outbreak of typhoid fever in 1905, concerning which a special report was made by Dr. Bushell Anningson and Professor Sims Woodhead. Subsequent reports were made to the Cambridge Town Council by the medical officer of health (Dr. Duncan Forbes), and at the request of the Senate of the university and the town council an inquiry into the question was held in February last, on behalf of the Local Government Board, by Dr. Theodore Thomson and Mr. P. M. Crosthwaite. In the report upon this inquiry, which has just been issued, the inspectors state that they do not consider there is risk of dangerous pollution of the water supply from the asylum sewage, for the field in which it is treated is nearly a mile distant from the sources of supply, and experiments with fluorescein made by Dr. Monckton Copeman in 1905 demonstrated that the flow of the underground water was very slow. The report points out that careful and competent observers have shown recently that the period of vitality of the bacillus of typhoid fever in water is of short duration. With regard to the possibility of pollution from the villages of Cherry Hinton and Fulbourn a very different opinion is expressed. In both places there are inadequate and imperfect sewers, and many of the houses have connected with them cesspits which leak into the surrounding ground. The inspectors therefore express the opinion that in order to secure from contamination the whole of the water to the town of Cambridge the whole of the supply which is derived from the Lower Chalk should be abandoned and only that should be utilized which is obtained from the Greensand, although they are careful to point out that supplies from the Chalk may be resorted to if these can be obtained from districts not open to the risk of dangerous pollution.

A HEREDITARY barony has been conferred on Professor von Koranyi on the occasion of his retirement. This is said to be the first time such a distinction has been conferred on a Hungarian physician.

THE *London Gazette* of December 25th, 1908, announces that the King has been pleased to

appoint Harold Robert Dacre Spitta, M.D., B.S., D.P.H.Camb., to be Bacteriologist to His Majesty's Household.

KING EDWARD'S Hospital Fund, the Metropolitan Hospital Sunday Fund, and the Hospital Saturday Fund have issued a fresh circular upon the revised uniform system of accounts. The circular, which has been drafted with the advice and approval of Mr. John G. Griffiths, F.C.A., takes the form of supplementary notes dealing with questions which have arisen out of the first year's experience of the revised system, and includes amended forms of income and expenditure account, balance-sheet and statistical tables of expenditure upon in-patients and out-patients. The amended regulations are binding upon institutions applying for grants from either of the Funds.

At a special general meeting of the Metropolitan Counties Branch on December 30th, 1908, under the chairmanship of Sir Victor Horsley, President of the Branch, a motion was made to instruct the Branch Council to petition the Privy Council with a view to securing such amendments in the Charter as will provide (1) that a Referendum be taken on the decision of the Council, and (2) that it be taken by means of a letter to every member of the Association. Subsequently the following amendment, moved by Dr. Lauriston Shaw, seconded by Dr. Hugh Ker, was adopted by a large majority: "That this meeting of 'the Metropolitan Counties Branch, recognizing that 'the provisions of the Charter as finally drafted are 'the outcome of exhaustive discussion and of ultimate agreement by the properly constituted authorities of the Association, and being confident that any 'reasonable changes subsequently asked for by the 'Association will not be refused by the Privy Council, 'is of opinion that the best interests of the Association demand that every member should loyally 'support the application now being made, and should 'postpone all attempts to obtain amendments of 'the Ordinances until the Charter has been formally 'granted.'"

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Parliamentary Session.

THE record of the session of 1908 presents many features of interest. In the first place it was very prolonged, for, beginning in January it ended only on December 21st, and Parliament sat in eleven months out of the twelve, although only one day was so occupied in August. In spite of notable failures to pass Government measures it was a productive year as regards legislation; out of 308 bills introduced 73 became law, and private members succeeded in passing 16 out of the 230 measures proposed by them. The 57 Acts which the Government have added to the Statute Book out of 78 introduced comprise several of first class importance. Those dealing with Old Age Pensions, Irish Universities, the Port of London, the Hours of Coal Miners, the Prevention of Crime, Scottish Education, and Children, make a total which would distinguish any session of recent years. The failure of the Licensing Bill in the Lords and the rejection of two Scottish Land Bills by the same House, added to the withdrawal of the Housing and Town Planning and Education Bills, must be counted on the other side as disappointments, some of which may be remedied next year.

The Commons indeed were promised an early re-introduction of the Housing Bill, and as this measure contains many proposals calculated to improve public health, and proposes to require the appointment of county medical officers of health in every county with security of tenure and wide powers of supervision, the profession will anxiously look forward to its early reappearance. In the interests of housing and public health, which are inseparably connected, it is the duty of the Cabinet to see that the weeks of patient labour spent on this Bill in the Grand Committee should not be lost.

The Children Act, which is likely to prove a valuable addition to the Statute Book, also occupied a Grand Committee for many weeks. In this case prolonged labour has met its reward in the enactment of provisions calculated to safeguard infant and juvenile life and add to the well-being of future generations.

In the provision of old age pensions for persons of 70 years and upwards the Government have in the same spirit of State beneficence dealt with the other extreme of human existence. These two Acts are alone sufficient to make the Session of 1908 memorable.

In their list of successes the Government have to be credited with the Tuberculosis Prevention (Ireland), the Lunacy, the Poisons and Pharmacy, the Public Health (Markets), and the White Phosphorus Matches Prohibition Acts. All these will prove useful, and the first-named will be watched with special attention as an experiment made to stamp out the scourge of tuberculosis in Ireland, where the death-toll is greatest. Phosphorus necrosis will also disappear under the provisions of the Act prohibiting the use of white phosphorus.

The enactments about markets and lunacy, however, deal with administrative details less directly touching on medical interests.

The Poisons and Pharmacy Act settles a long-standing dispute as to the position of companies trading as chemists and druggists. The compromise arrived at requires the drug stores to have a qualified chemist in charge of each dispensing department, and also a qualified chemist as the general manager. This company trading in connexion with callings that are founded on special and expert knowledge is not to the advantage of the public, and any extension of it in the direction of medical practice will have to be jealously watched and prevented.

The sixteen Acts passed by private members have little or no relation to public health; and only two—the Coroners (Ireland) Act and the Housing (Ireland) Act—are remotely connected with medical work. In the list of 230 bills introduced by private members, there are, however, many of much importance to the profession. For instance, there were no less than six bills brought in to suppress experiments on animals, and late one night in February Sir F. Banbury got an opportunity of moving the second reading of the Dogs Protection Bill. An Irish member, Mr. Mooney, opposed the motion, and in spite of an attempt to invoke the closure, the bill was talked out. This incident enforces the lesson of constant vigilance, for the question will have to be debated and decided at no distant date.

There were three bills for the registration of nurses before Parliament this session, and one of them passed the House of Lords, but came down to the Commons too late to make progress. Next year this bill may have more success.

There were some half-dozen proposals dealing with public health, one dealing with water rights, one with sewers and drains, and one, the Public Health Officers Bill, which seeks to give security of tenure to medical officers of health and sanitary inspectors. This measure, which has been introduced for many years, has at all events educated opinion to some extent, as its principle has been partially adopted in the Housing Bill of the Government. The question of death registration and certification seems likely to attract attention in an early session, for two bills on this subject were introduced in 1908. A bill which dealt with coroners' inquests and proposed to abolish, as far as jurors were concerned, the viewing of the body, had an unusually hard fate, as it passed all its stages in the Commons fairly early, but could never get a third reading. Sir John Tuke again introduced his measure to prohibit medical practice by companies, and Mr. Cathcart Wason

the Parochial Medical Officers (Scotland) Bill, but neither obtained a second reading.

Infant Life Protection interested several members, and so did the Purity of Milk Supply, for which Mr. Watt introduced proposals to apply to Scotland. We cannot help thinking that in this matter the Local Government Board have been remiss. Early in the session a bill was promised by Lord Carrington in the Lords; Mr. Burns, repeatedly questioned on the subject, led the House to expect at least the introduction of a bill, but nothing was done. It is a question of great urgency in connexion with public health and the prevention of tuberculosis, and ought to be dealt with at the earliest date next session. As far back as last March there was a debate of much value on the clauses dealing with milk supply in the London County Council (General Powers) Bill, and the President of the Local Government Board then gave pledges of legislation which urgently need to be fulfilled.

As in other years, questions were the means by which attention was called to many medical topics, and in this way very useful work was done by many members. These inquiries took a very wide range, as will be seen from the following list of some of the subjects on which Ministers were interrogated: Sleeping sickness, British and German death-rates, lead poisoning, tuberculous meat, anthrax, vivisection, Malta fever, the Inebriate Acts, milk supply, the College of Surgeons and its members, first-aid certificates, industrial accidents, glanders, nurses and medical certificates, the death-rate on the Rand, factory inspection, beer and lunacy, vaccination prosecutions, beri-beri, pensions and out-relief, rabies, ventilation in the House of Commons, infantile ophthalmia, vaccination fees and Poor-law salaries, female medical officers at the Post Office, London ambulances, the Notification of Births Act, the new buildings of the British Medical Association, London University, the telephone and disease, tuberculosis in the army, medical referees, training of nurses, standards for food preservatives, medical inspection, medical fees under the Midwives Act, deaths under anaesthetics, vaccination officers' fees, plague, Belfast Health Commission, Poor-law children, cancer research, etc. Questions are becoming more and more important in the Commons as a means of directing attention to specified subjects and as an effective method of educating opinion both in the House and outside. Medical men would do well to communicate from time to time with their representatives in Parliament with a view to having questions put on matters affecting the profession.

The much greater use of grand committees for the committee stage of bills has deprived the proceedings, as published, of many interesting debates on some special topics. When the new regulations for reporting day by day the proceedings of Parliament come into operation this will be to some extent remedied. In 1908 there were certainly many discussions in committee on the Children Bill, the Housing Bill, and the Tuberculosis Prevention Bill which were of medical importance. In the general debates in the two Chambers there were not as many references to medical questions as in some sessions. We miss the old-fashioned controversy over the Army Medical Department, which was not adequately replaced this year by the short but interesting criticism of the Naval Medical Establishment. There was, as already said, a good discussion on milk supply on one occasion which we trust will bear fruit hereafter, and on the Local Government Board Vote there was a good deal of comment made on the Tuberculosis Commission and its work and expenditure. The Home Office Vote also called forth from its perennial critic, Sir Charles Dilke, some very interesting remarks on child labour in factories, and the baneful effect of the employment of married women in factories on infantile mortality. There was also, before the Whitsuntide recess, an interesting conversation on the increase of accidents under the Factory and Workshops Act, and a committee was promised to investigate and report.

Looking at the work of the Session as a whole, it may be regarded as affording plenty of evidence of the vitality of medical questions in both Chambers. If topics for larger treatment have been lacking, all the points bearing on the profession and on public health have found their advocates and critics, who have efficiently safeguarded the general weal.

England and Wales.

FROM OUR SPECIAL CORRESPONDENTS.

MANCHESTER AND SALFORD

THE MANCHESTER UNIVERSITY UNION.

THE officials of the Manchester University Union must be congratulated on the success of the annual soiree held at the university. The guests were received by the Vice-Chancellor, Dr. A. Hopkinson, and Mrs. Hertz, and by the Chairman of the Union, Mr. A. Haworth, and also the Chairman of the Women's Union, Miss M. McNicol. There was the usual comprehensive list of entertainments going on in almost every part of the college, though, perhaps, the scientific exhibits were not so numerous as formerly. Exhibitions of fancy glass blowing and demonstrations by a potter of the use of the potter's wheel, and numerous biological and chemical exhibits, served to fill up the intervals between other entertainments of a less scientific character. The University Dramatic Society gave an excellent rendering of a costume play—*Hal, the Highwayman*—while in another place Mr. Hamilton Irving gave delight with his lightning sketches. It is expected that the union will take up its abode in its new home by the end of the next session. The new premises will cost about £9,850, exclusive of furnishing, and the committee, of which Sir William Mather is chairman, has collected about £8,400. It is calculated that about £2,700 more will be needed to open the new building properly furnished and free of debt. As the Chairman of the Union, Mr. Haworth, said: "In a non-residential university like that of Manchester, where only 12 per cent. of the student live together, a large and well-equipped union is of first importance. A common ground, where men of different schools may meet together within the university, is not merely socially desirable, but is an indispensable feature of true academic life."

INFECTIOUS DISEASE CERTIFICATES.

It is only fair to the sanitary officials of the Swinton Urban District Council to suppose that they can hardly have realized the full import of a certificate which they are asking medical men to sign who have been attending infectious diseases. The request that the certificate should be signed comes from the inspector of nuisances at the District Council offices at Swinton, and the certificate is in something like the following terms: "I hereby certify that I have this day examined ———, residing at ———, and find him *entirely free from infection*, and in my opinion the room or rooms may now be disinfected. Signed ———, medical practitioner in attendance." It is to be hoped that no medical man will in a thoughtless moment append his signature to any document stating in such definite terms that any patient is "entirely free from infection." It is unfortunately the fact that there is still great uncertainty about the duration of infection in certain diseases, and it is practically impossible to tell when a patient is quite free from infection after either scarlet fever or enteric fever. The discovery of so-called "carriers" of these diseases, who, when they are apparently quite well themselves, remain capable of carrying and conveying to others the infection for an almost indefinite period should warn medical men against too dogmatic statements not justified by the present state of knowledge. Another consideration should also weigh, for such a certificate might well afford grounds for an action at law if another case should occur in a house where a previous patient had been unequivocally declared to be entirely free from infection. The number of return cases that occur after dismissal from fever hospitals should be a warning that with the greatest care and the utmost skill it is as yet not possible to say when a patient is free from infection. Return cases of scarlet fever are the greatest bugbear of the hospitals, and reduce the medical staff almost to despair at times, and the medical superintendent of at any rate the Salford Sanatorium has for a long time very wisely refused to sign any such definite certificate as that which the Swinton sanitary officials ask for.

AMBULANCE ARRANGEMENTS IN TIME OF WAR.

The annual prize giving in connexion with the East Lancashire Territorial Division of the Field Ambulance took place on December 19th, 1908, at the Manchester head quarters. Lieutenant-Colonel J. Bently Mann presided, and said that under the Territorial scheme three field ambulances were being organized, commanded by Colonel Fairclough, Colonel J. W. Smith, and himself. Each of these ambulances had a strength of 230 officers and men, including transport sections. Two of the sections were trained at the Manchester head quarters, and each field ambulance had one outlying section stationed respectively at Bolton, Burnley, and Bury. The general hospital for the use of the division in time of war consisted of 500 beds; it was under the superintendence of Professor Wright. In addition sanitary squads for field work, both in peace and war, were being organized, but so far the names of 26 men only had been received, whereas a detachment should consist of 98 men. Their duties were to prevent disease in the training camps by supervising the water supply and general arrangements. The nursing staff was being organized by the matron of the Manchester Royal Infirmary, and a large number of physicians and surgeons of Manchester and the surrounding district had volunteered for service in the general hospital in case of emergency. Colonel Coates, C.B., the Administrative Medical Officer, in distributing the prizes, said there was a great need of nurses who, when war broke out, would undertake nursing in the general hospital. There was a good deal of misapprehension regarding this hospital. There was no intention of using the new infirmary or even the old infirmary, but in time of war any buildings might be commandeered, even the Cathedral or the Town Hall, or the Free Trade Hall, in fact any building that would be suitable for a hospital, but as a matter of fact the general hospital would consist of tents pitched on some suitable site such as the Plattfields. The equipment was already arranged for and negotiations were about to be made with certain firms to supply anything requisite on the shortest notice. Colonel Fry complimented the corps on its efficiency and, with the previous speakers, recognized the soundness of the Territorial scheme. To-day, he said, the defence force was really organized, whereas formerly it was all disorganized. He emphasized the great importance of the medical units on the field of action and mentioned the prospect of divisional training next year on Salisbury Plain.

LEEDS.

ANNUAL DINNER OF PAST AND PRESENT STUDENTS.

The weather on the occasion of the thirtieth annual dinner of the past and present students of the Leeds School of Medicine was most unpropitious, for Leeds, like many other places in the country, was at that time enshrouded in a dense fog of a peculiarly penetrating character. Happily there was some lessening of its intensity in the latter hours of the afternoon, but it says much for the loyalty and enthusiasm of the men that there was such a good attendance, and every one regarded the gathering, at which Mr. Moynihan took the chair, as one of the most successful that had ever been held. Among the guests was the Lord Mayor, Mr. F. J. Kitson, who is a member of the Board of the Infirmary, and students representative of the sister universities of Manchester and Liverpool.

THE POST-GRADUATE COURSE.

The second term of the post graduate course at the Leeds Public Dispensary commences on January 19th, when the first of the weekly clinical demonstrations will be given. Of these there will be ten. Of the special short courses announced, there were held during the last term one on diseases of the larynx, and a practical course on clinical pathology, dealing especially with bacteriology. Two special courses will be begun at the opening of the term, namely, on ophthalmology, and the histological and chemical part of the course on clinical pathology. As soon as a sufficient number of applications for admission to the other courses are obtained, these will also be commenced. The special courses announced deal with diseases of the heart, fractures and dislocations, gall stones, methods of physical examination of the abdomen, organic nervous

diseases, and chronic renal disease. Full particulars may be obtained from the Honorary Secretary, Post graduate Course, Leeds Public Dispensary.

THE LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

A special general meeting of this society will be held on the evening of January 22nd to consider a recommendation of the committee that one of the rules should be altered. The rule as at present framed is, "Any duly qualified medical practitioner desirous of becoming a member of the society shall be proposed and seconded at a general or ordinary meeting," etc., and it is recommended that the rule should read, "*Duly qualified medical practitioners, including women*, desirous of becoming members," etc. It might, of course, be argued that the term "qualified medical practitioners" includes women, and, indeed, the action of the association on former occasions would seem to imply that the officials read the rules in this sense, for on two occasions—twenty-three years and some five years ago respectively—women were duly proposed, seconded, and balloted for. At the time, however, when the society was formed and the rules drawn up this question did not arise, and therefore the committee is wise in desiring that the rule should be quite definite. The hope must be expressed that the recommendation of the committee will be ratified by the members, for there does not seem any reason why women, who are now admitted to the ranks of the profession, should be debarred from the advantages of membership of such a society.

LIVERPOOL.

THE COUNTRY HOSPITAL FOR CHILDREN.

The Country Hospital for Children at Heswall has now been in existence for nine years, and so far as the means at the disposal of the committee have allowed has been doing a highly beneficent work on children who have been the subjects of chronic disease. At an early date a new building, which is nearly completed, will be opened for the reception of patients. It stands on ten acres of land, and consists of an administrative block, containing a committee-room, accommodation for the resident medical officers and the matron, and rooms for a staff of twenty-seven nurses. When the hospital is finished there will be three blocks for patients, but at present only the central block is completed. This block consists of three floors and a basement, each having a corridor measuring 279 ft. by 11 ft., and from it access is gained to the large dining and play rooms, which for the present are fitted as wards. There is a fine operating theatre on the second floor. The hospital is well provided with lifts, all worked by electric power. There is a bed lift, communicating with the first and second floors, and with the theatre; on the ground floor its entrance is so situated that the children from any wards can be immediately taken into the hospital grounds. There are service lifts for food, coal, and stores, the latter extending from the stores receiving room on the ground floor to the store-rooms, which are on the top floor adjacent to the kitchen. The electricity for power and lighting purposes is produced in a special outbuilding near to the laundry, which it supplies. It is proposed to proceed at once with the building of the remaining two blocks. The leading principles kept in view in the foundation and development of the country hospital have been that the institution should be in the country; that it should be conducted on the lines of a hospital in which active medical and surgical treatment could be carried out; and that there should be no time limit, all the patients being retained until recovery or permanent benefit has been established.

NEW DENTAL HOSPITAL.

The Royal Infirmary Medical School, many years before its expansion into the University College, recognized the importance of systematic teaching in dentistry, and as long ago as 1867 appointed the late Mr. Snape lecturer on dental surgery. This was eleven years before the passing of the Dental Act, which made systematic teaching compulsory. The foundation of the present dental hospital in Mount Pleasant was still earlier, its first official year being 1861; its origin, however, was still further back, as it arose before that date through the agency of a dental surgeon, Mr. W. J. Newman, who gave gratuitous dental

aid to the poor in his house in Russell Street. In the first year of the existence of the Dental Hospital 696 patients were treated, and in 1907 the number was 25,727. The work is steadily increasing, and the dental school has in recent years come much to the front in the University; it is not surprising, therefore, that the old buildings in Mount Pleasant have for some time been found altogether inadequate.

An admirable site for a new hospital has been found at the corner of Pembroke Place and Boundary Place, on a frequented tram route, and adjacent to the university and the Royal Infirmary. When completed the hospital will be equipped with all the most modern appliances. The cost of this important work is fixed at the modest sum of £10,000 for building and equipment, and of this over £7,500 have already been given or promised. Hospital physicians and all medical practitioners concerned with the health of the working classes will take more than a friendly interest in the progress of this undertaking. Much praise is due to Mr. W. H. Gilmour, the warden of the hospital and the representative of the dental school on the Medical Faculty, for his enthusiastic labour in promoting the scheme which is now about to be taken in hand. Great credit and thanks are also due to Professor Paterson, the Professor of Anatomy, the treasurer of the Dental Hospital, who has cordially supported the movement for a new building, and has worked hard to raise the necessary funds. The Earl of Derby, president of the hospital, has consented to lay the foundation stone of the new building on January 16th. The architect is Mr. G. de C. Fraser.

WALES.

AMBULANCE ASSOCIATION.

THE annual report of the Glamorgan County Centre of the St. John Ambulance Association, just issued by the honorary secretary, Mr. Herbert Lewis of Cardiff, gives some interesting details of the local growth of an excellent movement. In 1907-8, 75 ambulance classes were held in Glamorgan, attended by 2,702 students. These were conducted under the Glamorgan County Council Education Committee, and Government grants were paid on the results. In addition, there were 50 private classes, with 1,200 students, and 1,627 obtained certificates, 326 vouchers, 185 medallions, and 60 secured labels. Since April, 1908, no fewer than 112 candidates have been instructed and examined by this centre. The report concludes:

The appeal for funds to enable the centre to purchase a motor ambulance car for use in Cardiff and the South Wales coalfield, as far west as Bridgend, has been generously responded to, and a sum of £425 14s. has been promised in donations towards the purchase of the car, and a sum of £102 12s. subscribed towards the maintenance and upkeep, to which Mr. John Cory has contributed £200.

The Cardiff City Council has promised to house and work this car, free of cost, for the first twelve months. The president is Sir W. T. Lewis, the patrons are the Marquis of Bute and the Earl of Plymouth, and the list of vice-presidents and members of the committee, of which the Lord Mayor of Cardiff is chairman, includes a large number of the prominent people connected with the coal, shipping, and other industries. The honorary treasurer is Dr. Thomas Wallace, Newport Road, Cardiff.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

THE INEBRIATES ACTS.

DR. C. DUNLOP, Inspector for Scotland under the Inebriates Acts, has recently issued his report for 1907.

The numbers admitted into licensed retreats, certified reformatories, and the State reformatory, were each smaller in 1907 than in 1906. This diminution was, it is stated, largely due to a resolution passed early in the year by the managers of the Girgenti Reformatory that they would not admit any fresh cases. The managers of that reformatory, the Town Council of Glasgow, for some years past had been pressing for certain amendments of the Inebriates Acts, and partly because the Government had taken no action on

their recommendations, and partly because they received notice that the Treasury contribution towards the cost of maintenance in their reformatory was to be reduced from 10s. 6d. a week to 7s. a week, they decided to close the institution. The number of direct admissions to the State reformatory was only 8, against 20 in 1906. The total available accommodation for the treatment of the habitual inebriate in Scotland at the commencement of the year in institutions under inspection amounted to 214 beds, there being three licensed retreats with accommodation for 34 men and 32 women, five certified reformatories with accommodation for 10 men and 105 women, and one State reformatory for 9 men and 23 women. At the commencement of the year the total number of patients and inmates was 157, of whom 36 were in retreats, 75 in certified reformatories, 28 in the State reformatory, and 18 temporarily absent from reformatories. During the year 110 were received into licensed retreats, 34 (4 men and 30 women) into certified reformatories, and 8—all women—into the State reformatory. The admissions to retreats were 10 fewer than in the previous year. Admissions to certified reformatories were also 10 fewer, and direct admissions to the State reformatory 12 fewer than in that year. The men admitted to licensed retreats were 21 fewer than in 1906, and those admitted into the State reformatory 7 fewer. The number of women admitted to certified reformatories was the same as in 1906, while those admitted to retreats were 11 more than in that year. Discharges numbered 88; of these 57 were from retreats, 24 from certified reformatories, and 7 from the State reformatory. At the end of the year the retreat patients and reformatory inmates numbered 179; of these 47—39 men and 8 women—were in retreats; 3 men and 71 women in certified reformatories, 10 men and 25 women in the State reformatory, and 23 temporarily absent. The net cost of detention of inmates—extraordinary expenditure excluded—varied from 7s. per inmate per week in Aberdeen Reformatory, to 30s. 8d. in the Lanarkshire Reformatory. In Greenock Reformatory it was 9s. 1d., and in Girgenti Reformatory 20s. 6d. The average net cost of all inmates in these four certified reformatories amounted to 15s. 5d. The inmates' labour produced in Aberdeen Reformatory an average sum of 10s. 4d. per inmate a week, and in Greenock Reformatory 3s. 9d.

Dr. Dunlop states that the result of treatment in the inebriate reformatories in the certified as well as in the State reformatory continued to show about the same amount of success as formerly. In the majority of cases the inmates soon after their discharge relapsed into drunken habits, and as curative or reformatory institutions the value of the reformatories had been found to be limited.

HOMOEOPATHY IN GLASGOW.

Homoeopathy seems to have a struggle for existence in Glasgow. A public meeting was held recently to endeavour to promote the re-establishment of a homoeopathic dispensary. The chairman said that the object of the meeting was to try and extend the benefits of homoeopathic treatment to a much wider circle. Dr. R. Gibson Miller moved a resolution approving the suggestion to establish the dispensary. He remarked that about ten or fifteen years ago there was such an institution, which made out about 54,000 prescriptions annually, but there were not enough doctors to carry on the work. Now, he was glad to say, they had in Glasgow and vicinity five or six homoeopathic doctors willing to go on with the work.

EXAMINATION OF NURSES BY THE LOCAL GOVERNMENT BOARD.

The second examination for the certificates of the Local Government Board of Scotland was held recently in Glasgow. Nineteen candidates presented themselves for the final surgical and medical examination. The examiners were Dr. George Gibson, Edinburgh; Dr. D. J. Macintosh, Western Infirmary, Glasgow; and Dr. Johnston, Superintendent of the Eastern and Western Districts Hospitals, Glasgow. The practical part of the examination was conducted by the matrons of the Western Infirmary and Eastern District Hospital, Glasgow. This is a new departure on the part of the Local Government Board, and is intended for the nurses employed in parochial infirmaries and poorhouses, thereby insuring that the inmates of these institutions will get the benefit of thoroughly trained nurses.

THE LATE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

There has been placed in the Church of St. John the Evangelist at Edinburgh a memorial brass bearing the simple legend: "In loving memory of Charles E. Underhill, M.B., P.R.C.P.E., born March 8, 1845, departed this life April 24, 1908."

Ireland.

[FROM OUR SPECIAL CORRESPONDENT.]

IRISH IN THE NATIONAL UNIVERSITY.

The senate of the new National University has not yet settled the question of compulsory Irish at the matriculation and at other examinations up to the point of specialization. The new Chancellor, Archbishop Walsh, is said to be opposed to the proposal, but it is believed that the senate is rather evenly divided. The correspondence which has appeared in the local newspapers shows by its language how very angrily the dispute is being carried on, for, while some see in the proposals another proof of a regenerating nation, others see only a proof of inexcusable blundering. The Roman Catholic bishops have not as a body expressed their views in public, but one of them, Dr. Clancy, enters a protest against the tone of the correspondence.

The idea, he says, of branding the senate, of which His Grace the Archbishop of Dublin is president, as "West British," and the university of which he is Chancellor as "a replica of Trinity College," is too absurd for even patient people to bear. Neither is it calculated to win sympathy for the policy of the Gaelic League that a man of Dr. Delany's pre-eminence in every educational work for the last fifty years should be made the victim of vituperative attacks from men whose services in the cause of education of any kind are in inverse ratio to the tone of self-sufficiency with which they write and speak. I fear the correspondence that has been published in connexion with this matter during the last few weeks will not raise the reputation of our people for deliberative discussion.

He holds that to insist on a knowledge of Irish in the case of all candidates from the inception of university work would inflict a serious injustice on a large number of colleges, and would practically exclude from university education, for four or five years, or otherwise drive into Trinity College, many of their best, most brilliant, and most promising young men and young women. He therefore advocated that, should a knowledge of Irish be made essential for matriculation, as he hoped it would, the colleges of the country should be allowed reasonable time to prepare for such an ordeal; and he suggested a period of four or five years as a minimum for this purpose.

And since, after the lapse of this period, it would set a premium on national apostasy, if Catholics, who are unwilling to face the drudgery of studying Irish, could gain easier admission to Trinity College than to the National University, I would advocate, in the second place, that the Gaelic League should bring all its influence during the next four or five years to bear upon the authorities of Trinity College with a view to have them adopt a similar rule in reference to the Dublin University.

The Gaelic League will have a hard task to convert the board of Trinity College to such action; but the fact that a suggestion of this sort should be made by a man who knows conditions as they are in Ireland shows how serious the question is.

THE HEALTH OF BELFAST.

The Belfast Health Commission appointed by the Local Government Board gave in its report about the middle of 1908. A joint report drawn up by three committees of the City Council in answer to the Commission's report was issued a few months later; in it the Citizens' Health Committee was pilloried as asking for and procuring an investigation which was expensive and did no good. The Citizens' Health Committee has now issued a rejoinder to the combined committees' report. The various questions which were submitted to Mr. Bryce, the ex-Chief Secretary for Ireland, and given as a basis and reason for inquiry, are taken in order, and in a parallel column are given the answers of the Commission. Every one has thus an opportunity of seeing at a glance the problems which appealed to the Citizens' Health Committee and the answers or solutions of the Commission. The important questions of typhoid fever, tuberculosis, the death-rate and

the population of Belfast, the measures taken by the health authorities to localize disease, the report of a previous inquiry, are also considered pretty fully. Finally, the conclusion is arrived at that the demand for an inquiry was perfectly legitimate, and that considerably more energy has been thrown into the working of the Health Department since the Commission sat, and that if the Department will seriously grapple with these questions it will find no more cordial supporters than the Citizens' Health Committee; the unwritten but evidently suggested inference is that if no serious attempt be made the vigorous attack will be continued till Belfast takes her place with other large towns in the advance of public hygiene.

Natal.

[FROM OUR SPECIAL CORRESPONDENT.]

COOLIE IMMIGRANTS.

A GOVERNMENT commission of inquiry has been appointed to examine into the question of indentured coolie labour in the Colony. The terms of reference amongst other clauses include the inquiring into, and advising upon, the medical supervision of indentured immigrants and the control by Government of medical officers employed in this work. The seven members of the Commission include five members of the Natal Legislature.

ANKYLOSTOMIASIS.

Ankylostomiasis, which is rife on several of the sugar estates, is attracting considerable attention and causing some alarm. The latrine system is being perfected in all places employing Indians, and in all infected centres of industry regular hospital treatment has been instituted, examination of new arrivals being carefully conducted. Precautions are also being taken to guard against overseas infection. Ankylostomiasis has now attacked Europeans, and the disease threatens to be a serious matter for the Colony.

Canada.

[FROM OUR SPECIAL CORRESPONDENT.]

TUBERCULOSIS EXHIBITION AND LECTURES.

The Montreal League for the Prevention of Tuberculosis, which was practically organized by Professor Adami some five years ago, has been doing quiet but steady work and gaining strength day by day; but the most important step in its history was taken when it was determined to educate the public by means of an exhibition, which was held in Montreal from November 17th to November 28th, 1908.

A special effort was made to reach the children, and lectures and demonstrations were arranged for their benefit. The school authorities co-operated with the committee, with the result that in one morning alone fifteen hundred were present.

It is estimated that between 4,000 and 5,000 citizens of Montreal daily availed themselves of the opportunity of becoming acquainted with the progress made in the fight against tuberculosis, as 55,000 attended in all. Speakers from Paris, New York, and Toronto, as well as from Montreal itself, delivered lectures in French, English, and Yiddish; and a large staff of nurses from the various city hospitals gave demonstrations in cooking, care of infants, care of milk, etc. The exhibition was formally opened on November 18th by His Excellency Earl Grey.

Dr. Herman Biggs (head of the Board of Health, New York) gave a most interesting history of the fight against tuberculosis in New York. In 1887 Dr. Biggs brought before the New York Board of Health a proposal for the scientific treatment of consumption. It was referred by the board to a committee of medical men, who reported that the time was not ripe for the introduction of such a measure. Again in 1893 Dr. Biggs brought up the matter, and finally a resolution was passed by the board declaring tuberculosis to be an infectious disease, and instituting certain measures for its prevention.

There were, in the first place, education of the poor; secondly, registration of cases, especially those in institutions; thirdly, visiting cases into the homes; fourthly, inspection of buildings vacated by tuberculous patients; and, lastly, the condemnation of buildings under order of the board in special cases. Registration of private patients was not at first made compulsory, as it was realized that there was a strong feeling against such registration. A few years later, however, the requirement of notification was extended to all physicians; and then trouble began. The doctors as a whole were opposed to the innovation, and fought the board even to the Legislature, but at the present time they were working in harmony with the Board of Health in reporting these cases. New York was an exceptionally difficult city to govern, as it contained sections more densely populated than any other place in the world; there were parts of the city where the population was 800 to 1,000 to the acre. What this meant might be realized when it was remembered that Whitechapel contained but 350 to 400 to the acre. However, their inhabitants were almost always foreigners and of the lowest classes, each speaking its own language—Greek, Slav, Czech, or Chinese—so that many of the circulars were printed in nine different tongues. One publication in the educational crusade was a catechism for school children; of this 700,000 copies were distributed this autumn. Lectures were given before social settlements and labour organizations, illustrated with stereopticon views. Literature of all kinds was widely disseminated, and the press was freely used for the purpose of popularizing knowledge of the subject. The second main feature of the campaign in New York was the notification of cases. This had been opposed on the ground that the patients were branded as lepers and placed outside of all society. This argument he considered to be nonsense. The notification was not public; it was for the Board of Health only, and if the case was in charge of a qualified physician who would direct proper precautions to be taken, the board left the case in his hands, and limited inquiries to every six months, to see how the patient was progressing, and whether the physician was prepared to continue his oversight. At the present time it was estimated that 95 per cent. of the cases were reported, or about 40,000 cases, of which some 30,000 were in the tenement district. Free examination of sputum was another feature, and whereas when this was first introduced but 500 specimens were examined, last year there were 27,000. House to house visitation by trained nurses was a means of keeping track of the spread of the disease. Eleven clinics were carried on in different parts of the city, and these were used for the distribution of eggs and milk, as well as medicines. Dr. Biggs thought that the construction of hospitals for advanced cases was the most important part of the work of the Board of Health, and that insubordinate cases should be detained by force. He thought that a few examples would soon put an end to the necessity of forcible removal. When a building was vacated by a tuberculous patient it was placarded until its owner had disinfected it and had done the necessary painting or kalsomining. Dr. Biggs closed his address by wishing every success to the movement in Montreal.

Dr. Dagenais, in moving a vote of thanks to Dr. Biggs, drew attention to the work that was being done in Montreal, and stated that it was hampered by lack of funds.

Dr. Hodgetts, of the Ontario Provincial Board of Health, in seconding the resolution, declared the need of Federal action to meet the evil, and gave a brief outline of a plan for the division of the expense.

Sir George Drummond, Dr. Yates, Dr. Adami, and Dr. Lachapelle spoke during the afternoon session.

The exhibition was well advertised, the press devoting several columns daily to a report of the proceedings, and the results were well shown in the numbers which attended. The exhibition itself was of the most practical nature, illustrating open tents, ventilation of rooms of all kinds, methods of sanitation and disinfection, the physiology of breathing, and many other similar matters. One thing, however, was noticeable, which is so often absent under such conditions—namely, adequate instruction. There was always a splendid staff of trained and efficient men and women in attendance who could and would explain things. Nothing was left undone to demonstrate the meaning of every article and point out the value of

every exhibit. Nothing was left to chance. The gospel of fresh air, sunshine, cleanliness, and good food was preached from every side, and it is impossible to think that an impression was not made.

The lantern lectures were not only scientific and accurate, but they were popular and most interesting. The children listened with attention, than which no better test could have been given of the value of these addresses. The demonstrations were carried out in detail before an appreciative audience every day, and talks, such as were given by Miss McNaughton and Mrs. Newcombe, were received with great enthusiasm.

The work was carried on in English and French, so that the whole of the city was interested in the exhibition at the same time, while one of the last lectures was in Yiddish, thus including one of the most important and populous sections of the city.

It need hardly be said that the committee has been delighted with the outcome of the venture and with the support they have had, not only from the medical profession but from the general public.

The results cannot be over-estimated, for although they may not be seen for some time to come, yet the educational value, more especially to the children, will be evident in the homes of those who as yet have not been impressed by the brilliant prospects for success from following methods thus popularized.

The results of the prize competition for the essays on tuberculosis by a scholar in any school in Montreal have not yet been published, but the fact that hundreds of papers have been received goes to show that the aim of the committee has not been amiss.

It is to be hoped that a similar exhibition will be attempted in other cities of the Dominion and that a like success may follow.

Special Correspondence.

PARIS.

Disturbances in the Latin Quarter.—Professor Osler.

Very serious disturbances occurred last week in the Quartier Latin, beginning on Monday morning, when the examining board, under the presidency of Professor Bouchard, assembled to hold the first examination of candidates for the certificate of admissibility to the competition for the posts of *professeur agrégé* in the different medical faculties in France. This new certificate of higher medical studies met with great opposition, as it tended to create a grade of qualified men above the ordinary doctor of medicine. At present all qualified men in France hold the State diploma of doctor of medicine, and the teaching staff in the faculties of medicine is selected as vacancies occur by competitive examination. The new certificate was intended to be given to qualified men who should pass a higher qualifying examination, the successful candidates being able to present themselves for the post of *professeur agrégé* as vacancies occurred in the subjects in which they might have specialized. Protests against this proposed creation of a higher class of practitioners had been presented by the two last *Congrès des Praticiens*, the petition being signed by no less than 12,000 medical men. The Medical Students' Association had also presented a petition, but both had remained without effect. Though 123 candidates presented themselves for examination, the majority as a protest did not sign the paper as being present. In the meanwhile an angry crowd collected outside the Faculty of Medicine, a large majority of those present being practitioners of 30 or 40 years of age. After hissing and booing, the crowd burst into the Faculty, and after doing much damage the examination was postponed till Thursday morning at 7.45 a.m. Meetings of protest were held on Tuesday and Wednesday, and each day the Faculty was guarded by police. On Thursday morning, in anticipation of fresh disturbances, strong bodies of police and a company of Republican Guards were posted as early as 6 a.m. in and around the Faculty of Medicine. At 8 a.m. the paper was set, but at 11.30 out of 123 candidates only 18 sent in any papers. Of the remainder some went away, but the majority stayed in the examination

room, sat on the tables, lit cigarettes, or played cards. Before 11 a.m. the crowd had reached sufficient proportions to attempt to tackle the cordons of police across the streets which barred all access to the Faculty of Medicine, and soon after there was a pitched battle, the students throwing eggs, potatoes, ink-pots, etc.; the windows of the Faculty were broken, but the police were reinforced and standing six deep withstood the charge of the students. In the afternoon, however, matters became much more serious, the crowd had grown much larger and the Director of the Police summoned the mounted Republican Guards, who charged several times on the Boulevard St. Germain. Though driven away from the neighbourhood of the Faculty of Medicine a band of students managed to penetrate into the Senate. A great number of students and police were injured. On Christmas Day M. Clemenceau, the Premier, who is a medical man, received M. Julien, the President of the Students' Association, and in the presence of M. Lepine, Prefect of Police, heard the accounts of the rioting. M. Julien protested also against the presence of detectives and police within the precincts of the Faculty of Medicine. M. Lepine said they had been sent on the written application of Professor Bouchard. M. Clemenceau disapproved of this, and gave a written order to M. Lepine that this should never occur again. M. Clemenceau received a written statement of the objections to the new system of examinations, and the question will be considered at a Cabinet Council. In the meanwhile the examinations are postponed. The Faculty has, however, closed the dissecting-rooms to first and second year students till March 1st, which means a loss of three months to all concerned. The Latin Quarter is now again quiet.

Professor William Osler, who read a paper on endocarditis before the society, has been made a corresponding member of the *Société Médicale des Hôpitaux de Paris*.

EGYPT.

The Cairo School of Medicine.

THE Cairo School of Medicine makes steady progress in popularity amongst the rising generation of natives. At the commencement of the winter session in October, 1908, an unusually large number of young men applied for permission to enter the school: 50 were admitted, that number being all that the school can accommodate, although many more applied; there were now 240 students enrolled. With a view to training some past students to become efficient teachers in the school two of the laboratory assistants have recently been sent to England for further post-graduate study, and two more will shortly follow, their places being temporarily filled by young men recently qualified, who will in time also be sent to England for further study. The examinations for first and second years men commenced on December 19th, 1908, and the final will be held on January 9th. Dr. Norman Moore of St. Bartholomew's Hospital has been appointed by the Conjoint Board in England to represent it this year as its delegate and supervisor of these examinations.

Correspondence.

THE CHARTER AND THE REFERENDUM.

SIR,—I see from the announcement in the *JOURNAL* of last week that a petition for a Charter has been lodged at the Privy Council. I think it well, therefore, to say that such petition has not received the signatures of the President, Past-President, or President-elect.

For my part I was anxious that the Branches should follow the example of the South-Western Branch and take a postal Referendum of the members, so that their wishes should be clearly expressed.

I am still desirous that other Branches should take the matter up.—I am, etc.,

SIMEON SNELL,
President, British Medical Association.

Sheffield, Dec. 30th, 1908.

SIR,—The following letter, with an accompanying post-card, was sent to every member of the Branch, and we now append the replies received to date:

British Medical Association,
Glasgow and West of Scotland Branch,
Glasgow, December 19th, 1908.

Dear Sir,—At a meeting of the Branch on the 16th inst., specially convened on a requisition from the North-Western Division, to consider the restrictions upon the use of the Referendum in the Charter as it now stands, the Secretaries were instructed to take a postal vote of the members of the Branch to ascertain whether it was their opinion that a Referendum should be taken (1) on the requisition of half the members of the Central Council present and voting at the meeting at which the question came up, and (2) that it should then be by letter addressed to every member of the Association.

We were instructed to add a few words of explanation. To members who have perused the numbers of the JOURNAL for October 31st, November 14th, 21st, 28th, December 5th and 12th, or who can refer to them, no explanation is necessary, as the questions at issue are fully discussed from every point of view in the correspondence columns of all these issues.

The position is, shortly, as follows:—
Under the Charter as finally amended at the Sheffield meeting, a two-thirds majority of the Council will be required to put the Referendum (or appeal to the membership of the Association) into operation. It has been pointed out that this means that, as one-third of the Council is to be elected by the Representative Body, all the other members of the Council would have to be unanimous, and all present, in order to carry a Referendum to the membership of the Association. Further, in the event of a Referendum being taken, all the members unable to attend a Divisional meeting would be disfranchised, no postal vote being provided for. It appears to be admitted that, as matters at present stand, about 90 per cent. of the members would be disfranchised under this arrangement.

We enclose herewith a post-card upon which we have respectfully to request that you will register your vote by a simple "Yes" or "No" in reply to each of the two questions submitted. We have also to urge that you will be so good as to return the post-card not later than Wednesday, 23rd cur.

Yours faithfully,

JAS. GRANT ANDREW,
WM. D. MACFARLANE, JR., Hon. Secs.

On the post-card:

1. Are you of opinion that a Referendum should be taken on a requisition of half the members of the Central Council present and voting at the meeting at which the question comes up?
2. Are you of opinion that the Referendum should be taken by letter addressed to every member of the Association?

An affirmative reply was given to both questions in 180 instances.

A negative reply to the first question and an affirmative to the second were given in 72 instances.

An affirmative answer to the first question and a negative to the second were given in 2 instances.

An affirmative reply to the second question alone was given in 19 instances.

A negative reply to both questions was given in 7 instances.

To the first question, therefore, there replied:

In the negative 73
In the affirmative... .. 182

So that there was, of those voting, a majority of 103 in favour of a Referendum being taken on the requisition of half the members of the Central Council present and voting at the meeting at which the question comes up; and to the second question there replied:

In the negative 9
In the affirmative... .. 271

—a majority of 262 in favour of the opinion that a Referendum should be by letter addressed to every member of the Association. There is membership in the Branch of 687; 290 members voted, or 40.7 per cent.—We are, etc.

JAS. GRANT ANDREW,
WM. D. MACFARLANE, JR.,

December 26th, 1908.

Hon. Secs.

SIR,—The members of the Midland Branch have had a circular sent to them somewhat similar to that forwarded to the members of the South-Western Branch, and have been asked to reply to the question:

Do you approve of the Branch Council taking, in conjunction with other Branches, the necessary steps to lay before the Privy Council their view that a Referendum should be taken on the requisition of half the Council, and then by letter addressed to every member of Association?

There are 535 members of the Branch. The result of the voting is as follows:

Approvals... .. 219
Disapprovals 7
Undecided 1
Away 1

—I am, etc.,

ROBERT SEVESTRE,

Leicester, Dec. 21st, 1908. Honorary Secretary, Midland Branch.

SIR,—The postal vote which has been taken of the Midland Branch I have had the opportunity of examining in detail, and, as it is desirable to throw all possible light on the various methods of taking a Referendum, I have studied the answers to this experimental vote carefully.

To begin with, there are 535 members of the Branch, and this list has been dissected to ascertain how many members live in county towns (where Divisional meetings are held) and how many live in country places. I find that 228 live in county towns, and these could register their vote personally, without any difficulty whatever, provided the time to do so was somewhat elastic. Against this number I find there are 307 members living in country districts, and to these it is a matter of sacrificing considerable time (to say nothing of some expense) in order to have their desires made known to the Association.

The recent poll only included 227 replies in all—that is, about 40 per cent. of the membership; but it must be granted that this is a great increase on the percentage who recorded the vote personally and under the stimulating influence of a Referendum!

Of these 227, county town members were 93, while the number from country places was 134. This demonstrates clearly, I take it, that the men are willing to take a share in responsible decisions provided they have the opportunity. It would be interesting to have the figures of other Branch votes worked out on similar lines.

I feel very strongly that the policy of the Association should be to get the men to become members, and, once having got them, to educate them to take an active interest in its affairs; but this must be a gradual process, for many of the questions are exceedingly difficult of solution, and the busy medical man has not much time to devote to the study of highly contentious issues.

I trust sincerely that no harm may result from the openly advocated policy of "shedding the leaves," and I should like to remind the author of the botanical simile that the leaves perform a vital function in the life-history of the tree—not more vital, however, than does a large and increasing membership of our Association.—I am, etc.,

Leicester, Dec. 23rd, 1908.

ASTLEY V. CLARKE.

SIR,—I beg to hand you a summary of the returns of the voting up to this date, which I have received from the six Branches that have taken postal Referenda:

	Approving Resolution of S.W. Branch.	Disapprov- ing Resolu- tion of S.W. Branch.	Neutral.	Strength of Branch.
Yorkshire	373	9	2	884
South-Western	346	3	4	457
Midland	218	7	1	535
Edinburgh	214	—	—	413
Oxford	180	3	1	285
Dorset and West Hants	116	2	1	215
	1,452	26	9	2,789

These are not to be regarded as final, since in some cases I am informed that votes are still coming in. It will, however, be observed that over 50 per cent. of members of these Branches have signified their approval of our procedure; whilst less than 1 per cent. have signified disapproval.—I am, etc.,

RUSSELL COOMBE,
Hon. Sec. South-Western Branch.

Exeter, Dec. 23th, 1908.

SIR.—After several years of hard work by many of our members; after innumerable meetings of committees, Divisions, Branches, councils, and Representatives; after endless discussions on the subject and much correspondence, often too acrimonious and too personal, in our JOURNAL, we have at last, with the kind help of the authorities, arrived at a form of Charter which, in the main, satisfies all of us, and which, we are told, is acceptable to the officers of the Crown. This draft Charter has been definitely passed by our Representative Meeting, and subsequently twice confirmed by our Council. And yet now, at the eleventh hour, when, I believe, the application for the Charter has actually been sent in, an attempt is being made from within our Association itself to wreck the scheme, to throw away all this work in the past, and to squander our money on a contest for a Charter which ought to have been unopposed.

And for what is this urgent opposition raised? The only objection put forward is in connexion with the Referendum. The two points in dispute are: (a) As to the majority required in the Council, before a Referendum can be taken, and (b) as to the manner in which this Referendum shall be taken. Now, it is really worth while, for the sake of these two simple points, to make ourselves a laughing-stock, as an Association that will not abide by the rules of its own making?

It stands to reason that in an association with many thousands of members, it is impossible that every individual should be satisfied with every detail of a complicated document like the draft Charter. There may be many who think that a bare majority of even a small meeting of the Council should be sufficient to call for a Referendum. But we must remember that this Referendum will be attended by considerable expense and delay, and that the Ordinance as it now stands only lays upon the Council the same limitation as is placed on the Representative Meeting when voting on matters of importance. There may also be many who feel that a Referendum is not satisfactory where only those votes are counted which are recorded at a Divisional meeting, and that something in the form of a "postal" vote would be better. But this method of taking a Referendum by votes at a Divisional meeting is not an innovation: it is the existing method under which the work of the Association has been done for years, the object being that no vote should be taken without the question having been fairly discussed. The need for the alteration of this cannot, therefore, be a matter of pressing urgency.

Whatever views we may hold on these disputed points, one thing is certain, the time for making alterations is not now. In accordance with the Articles of our Association at present in force, they might have been revised at any time up to the meeting of the Council following the Representative Meeting at Sheffield, or they may be amended at or after the next Representative Meeting. But any attempt to do so now is not in accordance with our Articles, and is therefore truly unconstitutional.

I believe that this unbusinesslike resistance to the legitimate acts of our governing bodies has arisen from the misconception that these points can never be altered if the Charter is granted now. This is quite untrue. Our Charter will consist of three sections

1. The Charter proper, which, when once granted, can only be altered by act of the King or Parliament.
2. The Ordinances, which can be altered at any time with the consent of the Privy Council, and we are advised that the Privy Council never make any difficulty when applied to by the constituted authority.
3. The By-laws, which may be altered by ourselves without application to any outside authority.

Now, the disputed points come in the Ordinances, so there would be no difficulty in their amendment at any future time.

Do let us sink our differences for the time, and appear to the world as a sane and united body—at any rate, till the Charter has been granted. After that let us fight out the question amongst ourselves, without inviting the world to watch us squabble.—I am, etc.,

Harrow, Dec. 18th, 1908.

ALFRED H. WILLIAMS.

SIR.—Under the Charter all power is given to the Representative Body, and the resolutions adopted unanimously at Dr. Davy's conference would, if carried out,

have taken away any cause for complaint that the Representatives do not represent the views of the great body of members.

1. *On the Point of New Departures of Policy.*—That a decision of the Representative Body to adopt for the furtherance of the objects of the Association any of the means specified in Clause 2 (2) of the Charter not previously adopted shall require confirmation by another Representative Meeting. If so confirmed the proposal will then come before the Council, which may take a Referendum. This would prevent "the promotion of the candidature of any member of the Association for Parliament or for any British (not colonial) legislative assembly" being adopted without full consideration. (The recent decision in the High Court will doubtless prevent this being included in the objects of our trades union.)

2. *On the Taking of a Referendum.*—That a Referendum shall be taken on the requisition of half the Council, and shall be by means of voting papers sent to every individual member of the Association. This would remedy the present unsatisfactory state of things, and would give every member a chance of recording his vote without the loss of time and expense incurred in attending Divisional meetings.

It is of course quite possible that even then a large number of Dr. Fothergill's "leaves" would not take the trouble to return the post-cards, but recent experience shows that a clear majority would record their votes, and those who did not take the trouble could not complain, as every one would have an equal chance.

3. *On the Election of Representatives of Divisions.*—That nominations should be received by a certain date, and, in case of a contest, that the election shall be by voting papers sent to each member of the Division. This, to my mind, is the most important of all, and would make the Representatives truly representative. Nomination would lead to competition. At a meeting when one man is proposed it is very invidious to get up and propose another, however much one felt the first man unsuitable; but no one would mind sending in a nomination, and by means of voting papers every one would get an equal chance, and it would be the fault of the members if they did not choose the best man.

It is true that this is to be optional under the Charter, but it should be compulsory, and reference to the SUPPLEMENT of August 2nd, 1908, will show that the very men who threw out this amendment were afraid to trust themselves to the suffrages of their constituents, and will take care the present system is continued at any rate in their Divisions. The members present at Dr. Davy's conference fully recognized the unsatisfactory condition now existing, and instances were given.

One gentleman stated that a meeting of the Division was called to elect a Representative. He attended and no one turned up, and he had to go out and get a couple of men to come in and form a meeting, one to propose and the other to second his re-election; and it is whispered that even in that model Division of all Divisions, Wandsworth Common, the attendance is not very great, except at feeding times, and that our great lawgiver does not represent many voters.

It is an undoubted fact that very few Divisions take the trouble to instruct their Representatives, and such a flood of matter has been poured out at head quarters that it has been impossible to go through half of the questions referred, and the custom, even in active Divisions, has been to consider one or two matters and then leave the rest to the discretion of the Representative, although few, I hope, adopt the methods of the Channel Islands Division which the Representative finds so satisfactory.

Now the Medical Secretary's office is fully staffed it is to be hoped that matters referred to the Divisions may come down more frequently and not all in a batch as heretofore.

I fear very few read the SUPPLEMENT of August 1st, 1908, and would advise every one to read it and compare with the letters in the JOURNAL: it will then be seen that the very men who now state it will be easy to amend the Ordinances as desired after the Charter is granted, resisted at Sheffield the introduction of the resolutions into the Ordinances on the ground that once introduced it would be almost impossible to vary or alter if desired.

In conclusion, I would state that in my opinion the peace of the Association depends greatly on the adoption of

nomination and election by voting papers of all Representatives compulsorily, and then there will be no reason to fear that the twelve Representatives on the Council elected by the Representatives will act as a body hostile to the members of Council elected by the Branches, because these twelve men are to be elected by single-member constituencies, consisting of one or more Branches grouped for that special purpose, by the Representatives of the Divisions included in the area thereof, and not by the Representatives as a body, so that if the Representatives themselves are chosen as the members of the Council elected by the Branch are now, they will be equally to be relied on as voicing the wishes of the members.

I hope steps may be taken to hold a conference in London, and that the South-Western Branch will see this is carried out shortly.—I am, etc.,

Wimborne, Dec. 21st, 1908.

C. H. W. PARKINSON.

MINISTRIES OF HEALING.

SIR,—Your carefully considered leading article in the JOURNAL of November 28th, 1908, on the above remarkable extension of medical practice suggests that the question of the systematic application of psychic force as a remedial agent is at least worthy of careful consideration. For several years while Physician to the Glasgow Royal Infirmary I made use of it in the wards under my charge. This was before I heard of the existence of Mrs. Eddy and her ways. I have recorded the results of my experience in the volume of the *Glasgow Hospital Reports* for 1889, and I had previously brought the subject before the International Medical Congress in Moscow.

I think I may best indicate the class of cases in which this method of treatment was employed, the procedure followed, and the results of the practice, by a quotation from the former of these papers:

The method of procedure is as follows: Sitting down opposite the patient, if in bed, or standing opposite her—for in most, but by no means all, cases it is a woman—if on foot, I require her to look steadily at my eyes. This frequently causes a difficulty at first, as there is a strong disposition in such cases for the patient to look down or aside, but on asking her resolutely she eventually complies with my request. Then continuing in a firm tone of voice and decided manner, I address her somewhat in the following terms: "You understand that these seizures, if subject to spasmodic or other form of attack, must stop." This I repeat, often modifying the remark, till I get the patient to say, "Yes, sir." Daily or every second day, at gradually increasing intervals, this formula is gone over, and even after the patients have left the infirmary I have required them to return once a week for several weeks, so as to maintain the controlling and fortifying influence on the mind and brain.

The results in most cases have been immediately successful, and have been observed by medical practitioners as well as students. It is not, however, sufficiently powerful in its action to cope with the more severe forms of neurotic disorder, such as those recorded in the early part of this paper. Its proper sphere of usefulness is in the slighter forms of derangement of the nervous system.

In another part of the same paper I mention that in one case of chronic melancholia the daily practice of psychic impressions by myself in the way described, so far as I could judge, clearly assisted ordinary general treatment in inducing recovery. I also state that as far back as 1871 I tried the effect of strong mental impression in insanity, and recorded my experience in the BRITISH MEDICAL JOURNAL for that year.

It is to be observed that throughout this letter I have used the words "psychic impression" or "psychic force" to designate this therapeutic measure. The first of these terms is preferable as it raises no question as to the nature of the action. Suggestion is much too mild in its significance; it seems to leave a choice to the patient. On the contrary, he or she is subjected to a dominating, compelling force, that of the operator's will, which produces a profound impression on the mind of the recipient. Doubtless, too, there is a corresponding cerebral change, probably a partial or even complete restoration to the normal condition.

I close these remarks by stating my conviction that both in hospital and private practice this psychic agent should be employed in suitable cases as an addition to ordinary medicinal and hygienic treatment. But besides, as you have said in the article referred to, the help which religious faith and spiritual teaching can give should be cordially welcomed.—I am, etc.,

Glasgow, Dec. 7th.

ALEXANDER ROBERTSON.

LACTIC ACID BACILLI.

SIR,—Dr. R. W. Allen's paper on lactic acid bacilli appeared in the BRITISH MEDICAL JOURNAL of November 28th at the moment when Major G. Dansey Browning and I were completing an inquiry into certain other aspects of the lactic acid bacillus treatment.

Our work leads us to believe that the liquid commercial preparations alone contain pure cultures of Bulgarian lactic acid bacilli, and that these are temporarily in a state of low vitality—the so-called *vie valente*—when grown at atmospheric temperature. Solid preparations, on the contrary, are invariably contaminated with spore-bearing and other organisms, which more or less rapidly overgrow the Bulgarian bacillus when cultivated at 37° C. We fully realize the danger of incubating possibly contaminated milk, despite the presence of added living lactic acid bacilli; and we think that this danger is necessarily much greater when non-vigorous bacterial growths are made use of.

We offer the following suggestion for administering lactic acid bacilli as a possible solution of this difficult question:

Obtain the Bulgarian bacillus in pure cultivation on a liquid medium (that is, a liquid commercial preparation).¹ Incubate this preparation for twenty-four hours, and then add it to the vehicle selected for administration. Of these, milk which has been boiled on water bath for an hour, sterilized whey, or malt extract solution appear to be the most suitable.

In the absence of an incubator, the unopened liquid preparation may be kept in a Thermos flask filled with water at 40°–57° C.

Unfortunately the liquid preparations remain active only for a short time, and young cultures can only be employed. In older cultures the amount of acid production is so considerable that the Bulgarian bacilli themselves are killed off. If, however, particles of solid calcium carbonate be added to the cultures containing the young bacilli no excessive acidity is developed, and the culture will remain active for a considerable period.—I am, etc.,

F. G. BUSHNELL, M.D.,

December 26th, 1908.

Sussex County Hospital, Brighton.

THE USE AND ABUSE OF THE CURETTE.

SIR,—Dr. Donald is right in his conjecture as to why I did not mention his name. I did not wish to attack him, but only what I conceive to be his erroneous opinions. And I did not criticize his treatment of individual cases. I am quite willing to believe that among the group of cases that he calls "endometritis in virgins," there may have been some of genuine dysmenorrhoea which were cured by the dilatation which went with the scraping and the packing; and also that in some of them there may have been adenomatous growths which it was good treatment to scrape away.

But as to the main issue, I am impenitent. Dr. Donald describes what he terms a "clinical type": young women with pain, worse when they menstruate, and leucorrhoea. In about half, he says, menstruation is increased. A symptom which is absent in half the cases can hardly be called typical. This clinical type he thinks is due to endometritis. The late Dr. Graily Hewitt used to take young women suffering from similar symptoms into a hospital or nursing home: he gave them rest, food, and sleep; he put a contorted bit of vulcanite into the vagina, and sent them home greatly improved in health. He thought that the illness was from antelexion, and that the improvement resulted from the bit of vulcanite in the vagina. A more recent eminent gynaecologist used to bewilder certain candidates at the examination hall by asking them questions about "chronic ovaritis." Many of them had never seen the disease diagnosed; and they were told by the examiner that it was the commonest disease to which women were subject. For this same clinical type ovaries have been removed because they were thought to be "sclero-cystic," or "cirrhotic." On this question I expressed my views at the meeting of the

¹ The liquid preparations examined by us were obtained from Messrs. Oppenheimer and Son, London, and from Messrs. Millet et Veillard, Paris.

British Medical Association at Oxford in 1904. I grant that in a few cases of this clinical type there may be some local disease requiring local treatment; but most cases of chronic pelvic pain in virgins are due to neurasthenia, and do not want either curetting, or pessaries, or removal of the ovaries.

Dr. Donald says that the leucorrhoea is uterine and not vaginal, because "the discharge was seen to be coming from the cervical canal." No doubt the cervical glands secrete; but does *all* the discharge come from the uterus? I think every general practitioner of experience knows that an astringent vaginal douche will almost always lessen or abolish leucorrhoea in a virgin, which is to me evidence that the bulk of leucorrhoeal discharge comes from the vagina and not from the uterus.

Dr. Donald regards as physical signs of, or causes of, disease, smallness of the cervix and antelexion. I suggest that he should ask the pathologist of the Manchester Royal Infirmary to look for specimens of disease produced by smallness of the cervix or acute antelexion. Acute antelexion is present in many nulliparae, and there are specimens in many museums. In all the specimens the canal is a gentle curve, with no more obstruction than there is in a bend of a river. Dr. Donald might also direct the attention of the pathologist to Dr. Bossi's "cochleate uterus," and ask him to find one.

Dr. Donald objects to the comparison of the cervix uteri with the lobule of the ear, because one is an unnecessary appendage, and the other the orifice of a secreting organ. The point of the comparison is that one is visible to everybody, while the other is only looked at in order to find some disease. But since he is not satisfied I will give him another. Tennyson describes one of his heroines as having a nose "tip-tilted like the petal of a flower." Between this and the aquiline beak of the "Iron Duke" there is a difference greater than is commonly seen between the cervixes of different virgins, but I have never heard rhinologists point out either shape as evidence of disease. I do not attach importance to slight changes in the size of the uterus. My own senses are not acute enough to make me certain of small changes in size felt through so thick an intermediate structure as the abdominal wall. It was by signs such as these that Apostoli persuaded himself that by electricity he produced absorption of fibroids, a thing that nowadays scarcely any one credits.

The remark about retroversion which Dr. Donald notices was only incidental, and not the main subject of my lecture. Retroversion is associated with prolapse, and therefore with pain, in much more than one case in ten, but in most of these it matters not how the uterus is lying. I have by numerical analysis of cases come to the conclusion that in about one case in ten a patient with retroversion of the uterus has pain that she would not have had if the uterus had not been retroverted. My statement as to the obstruction of the return of blood from the uterus by pressure of sharp utero-sacral ligaments rests on *post-mortem* evidence; a uterus has been seen with the marks of this pressure on it. The details on which these general statements are founded are given in papers published in the *Transactions of the Obstetrical Society of London*, vols. xxiv and xxxi.

Dr. Donald thinks there is a steady turn in the practice of gynaecologists, and a growing disinclination to treat "these patients" with pessaries. Since I began this letter I have been into two of the principal surgical instrument makers' shops in the West End of London and asked if there was any diminution in the sale of pessaries. Both said there was not; and one thought the tendency was in the opposite direction. The request that I should lecture on the use and abuse of the curette does not suggest a trend in favour of more frequent scraping.

I say nothing about dysmenorrhoea at present. I may at a future time do so.

Dr. Donald says that his views "have suffered considerable misrepresentation." If I am in any way responsible for this, I am sorry. But I am still unconvinced that endometritis exists in virgins, apart from new growths or accidental infection. I think that scraping the uterus to relieve pelvic pain in virgins is a mistake, and that the repetition of scraping which has failed to do good deserves to be called an "abuse."—I am, etc.,

London, W., Dec. 23rd, 1908.

G. E. HERMAN.

THE APPLICATION OF MENDELIAN RULES TO HUMAN INHERITANCE.

SIR,—I agree entirely with several statements made by Professor Karl Pearson in his criticism in your issue of December 5th, 1908, p. 1720, of my address on "Heredity," but there are some statements from which I dissent.

He says: "It seems to me very dangerous in the present state of our knowledge to accept any sweeping application of Mendelism." Some may infer from this that I have been guilty of such a fault; but, on the same page which contains the remark to which the professor specially objects, it will be found that I said: "We must, however, acknowledge that Mendelian laws seem to be inapplicable in certain cases of inherited disease and abnormalities"; therefore, I plead "not guilty."

As to Nettleship's chart of the night-blind family, it will be well to examine it further. The figures I gave were quoted from Nettleship's paper (page 8). I cannot quite see how Mr. Nettleship gets the 255. I find there are 274 individuals in the disease-bearing branches if we stop at, and include, the last abnormal (+ the brothers and sisters) in each line of descent. These "last abnormals" are conspicuously numerous in this family tree, and one would like to know the reason for this. Possibly it is analogous to some such coupling of factors as seems to cause the 9.3.1. ratio to be modified to 9.3.4. or 9.7.; or may it be that, just as a yellow pea is dominant to green, and a maple dominant to yellow, so in the human subject one normal may be recessive, whilst another normal is dominant to the abnormal? If this does happen, it may be that these "last abnormals" were recessive to the normals whom they married. Now, if each line of descent had stopped short at the last abnormal, the result would have been that 134 out of 274 descendants of Jean Nougaret were abnormal, and this gives a percentage of 48.9, a remarkably close approximation to the theoretical 50 per cent., so that "we must pause before we accept" Professor Pearson's statement that "Nettleship's pedigree goes a long way to prove that they (Mendel's rules) do not hold for night blindness."

The facts (1) that all Nougaret's three children were night blind, and (2) that the disease has only been transmitted by affected individuals are also in accord with Mendel's results.

Professor Pearson adds: "Similar criticism may be applied to more than one other case cited by Dr. Drinkwater." I will only refer to the cases of tylosis mentioned in Dr. Gessage's paper.¹ There are three charts given. The first shows 6 abnormals out of 10 individuals; the second, 15 out of 27. The third chart is particularly suggestive. Here the disease originated in a woman, who was a pure dominant, and transmitted the disease to every one of her twelve children; a married daughter, being heterozygous, transmitted it to exactly 50 per cent. of her children (3 out of 6). These facts are *perfectly* Mendelian, and agree with the rules $D \times R = D(R)$, and $D(R) \times R = D(R)$ and R in equal numbers.

In conclusion, I think that all who have studied the subject will agree with Professor Pearson in emphasizing "the urgency for collecting far more material." What we wish to arrive at is the truth.—I am, etc.,

Wrexham, Dec. 8th.

H. DRINKWATER.

THE HEART-INDEX INTERVAL IN AORTIC REGURGITATION.

SIR,—I read with much interest Dr. Broadbent's communication on this subject in the *Journal* of December 19th, 1908, as it recalls an old controversy which I thought was long since settled. I furnished complete proofs of the position maintained by Dr. Broadbent in an article published in the *British Medical Journal* in 1901, February 16th.

As Dr. Broadbent has not referred to my article in any way, I should like to point out that the *plus* or *minus* variations in the heart radial interval are in that article not only discussed but explained. I showed that the *plus* variation was not to be wholly explained by "the collapsed and empty state of the arteries between the beats, and partly to their large size and loss of tone," since these conditions do not invariably prevail in aortic regurgitation. I also showed that when these conditions did not prevail the absence of the prophymic interval in aortic regurgitation could give rise to a *minus* variation.

¹ *Quarterly Journal of Medicine*, April, 1908.

The chief interest of my article lay not only in the proof of these facts, but that I offered an additional explanation of the phenomenon of heart radial delay in these cases, one which had not been noticed before. This I may be permitted to state again.

In a normal heart the blood pressure in the ventricle at the beginning of systole is about 20 mm. Hg; in less than one-tenth of a second the intraventricular pressure is raised to 150 or 200 mm. Hg; the effect is a sudden impulse or "slap" against the ventricular surface of the aortic valves, and the wave created thereby is sudden and of great velocity—28 ft. per second (Von Frey).

In aortic regurgitation, when the intraventricular pressure at the onset of systole is already 150 mm. Hg or upwards, the contraction is more of the nature of a steady push against a weight, and the resulting wave, not being created by impact, is a slowly propagated wave—that is, one of very much less velocity.

The elucidation of this point is the main object of this paper.

I also point out that the propagation of nervous impulse through a hypertrophied heart is more slow, and the large mass would for physiological reasons contract more slowly.

Apart from this, the tracings I gave were complete and conclusive as to the matter of fact then in debate.—I am, etc.,

PAUL M. CHAPMAN, M.D., F.R.C.P.

Hereford, Dec. 21st, 1908.

THE NEW PROVIDENT DISPENSARY SCHEME AT BIRMINGHAM.

SIR,—With the exception of the last paragraph of his letter in the JOURNAL of December 26th, 1908, I think the majority of the general practitioners in Birmingham will agree with Dr. R. R. Giddings on the above subject. This scheme has not yet, thank God, received the sanction of any general meeting of the local doctors. It is the old "public medical service" scheme, which a year ago we thought had been decently interred by a decisive majority of the profession, which has been galvanized into life by Mr. Neville Chamberlain, with the assistance of some few members of the General Practitioners' Union, who seem determined to "cut prices" to make a fortune (?). The ostensible reason for reviving this scheme is to relieve the hospitals from trifling cases which should never go to them. These cases almost invariably belong to the thriftless and wholly improvident classes, hence the new institution—under the derivation, "Lucus a non lucendo"—is to be called the "Birmingham and District Provident Dispensary." Mr. Arthur Chamberlain kindly suggested that we should educate these people into coming to the new dispensary, and Dr. Abbott of Aston shrewdly asked whether this was to form part of the curriculum of the future medical student. The majority of us have enough to do without trying to educate the baser fellows of the working class in sobriety or thrift. These men tell you they "pay a penny a week to the hospitals and are entitled to go there," but if their employers were to ask them to work overtime for the same wages they would strike.

The thing that appeals to those members who have not given it the consideration it deserves is the 70 per cent. of the subscription which is to come to their pockets. This is the bunch of carrots held on a stick before the donkey's nose that makes him pick up his ears and gallop when he is not at all sure of getting it for his pains. You must catch your hare before you cook it, and I venture to prophesy that the number of improvident people who will be enticed to join this provident dispensary will be infinitesimally small when divided amongst even fifty practitioners. I consider the printing of the rules and sending forms applying for appointment as medical officer to this scheme, before it has been submitted to the vote of the local practitioners, smacks very much of the impertinence which prompted another Chamberlain to start the "Consultative Institute" without even sounding the members of the profession in this district.

This has, doubtless, been a famine year for the general practitioner, and the shortage of work has alarmed some men. In nearly forty years I never remember anything like it. But the work will not be always so, and I hope my fellow members will prefer fighting with adversity—a sight said to be fit for the gods—than that they should

drag their profession through the mire, and work for wages that an errand boy would despise.—I am, etc.,
Birmingham, Dec. 28th, 1908.
E. T. BULTON.

SIR,—As one who must bear some portion of the responsibility for starting the new provident dispensary in Birmingham, may I crave your indulgence to explain a few points in connexion with the scheme, on which Dr. R. R. Giddings comments so severely in your issue of December 26th, 1908?

This new provident dispensary arose out of an endeavour to curtail the steadily increasing pressure on the out-patient departments at the general hospitals, a pressure which it is thought may be relieved by referring trivial cases to other and more suitable sources of medical treatment; and, secondly, by educating the public to understand that in all their minor difficulties they should not necessarily at once go to a hospital, but that they could obtain efficient relief for most of their smaller medical and surgical ills elsewhere, thus leaving the hospitals to their more proper function of relieving graver ailments. The committees of hospitals, whilst quite willing to refer trivial cases elsewhere—for instance, to the existing dispensaries, to private clubs, or to private practitioners—felt that a hiatus existed in that many of the poorer people have hitherto made no provision for, and would not know where to seek, medical relief within their small means. It was to meet this class of case especially that a provident dispensary was initiated.

The payment per member per annum is fixed at 5s., of which 70 per cent. is to go to members of the staff, the remainder being reserved for the provision of medicines, dressings, etc., the payment of the dispensers, and for secretarial expenses. Members of the medical staff are thus relieved of all burdensome details. This plan was adopted by the committee, which is constituted as explained below, and a provision was inserted that if at the end of a year this arrangement is not found to be equitable it should then be reconsidered.

In the initial stage of the scheme, before any regular committee had come into existence, I pointed out to those who were discussing the matter that if any scheme was to succeed it must give an adequate representation of the medical profession on its governing body as the great guarantee against abuse. To show that this security has been obtained I may point to the constitution of the governing committee of the dispensary, which consists of 29 elected representatives, together with a chairman and an honorary secretary elected by the committee, thus making a total of 31. No less than 14 of these must invariably be medical men and others may be; at the present moment there are 2 additional medical representatives elected by general hospitals, thus giving medical men a majority on the governing body.

No wage limit has been adopted, because whatever rules were laid down they would frequently prove unworkable, but a guarantee against abuse of the scheme lies in

Rule 8 (b) "It shall be open to any medical officer to decline to accept any individual patient," and in Rule 11, "Admission.—Application for admission shall be made in the first instance through one of the medical staff, who shall deal with the case provisionally. He shall then report as to the advisability of the applicant being accepted or rejected, to the District Committee, who shall consider and decide upon the case at their next meeting."

I may explain that each District Committee consists of nine members of whom four must be members of the medical staff. If the members of the staff work loyally together no abuse should arise owing to persons, whose means make them unsuitable, taking advantage of this provident scheme.

Despite what Dr. Giddings regards as Gilbertian humour I am glad to say that the success of the scheme as far as the staff is concerned is already assured, and that it consists of registered medical men of good repute.

May I, in conclusion, express the opinion I have long held that each great centre of the community must find its own remedy for hospital abuse and similar medical ills, and that what may be suitable and applicable in one great city may not be so in another, owing to the variations in hospital, dispensary, and other arrange-

ments? We in Birmingham are now endeavouring to work out our own salvation.—I am, etc.,

Birmingham, Dec. 29th, 1908.

GILBERT BARLING.

THE STATE REGISTRATION OF NURSES.

SIR.—In the JOURNAL of December 26th, 1908, Dr. Shuttleworth, speaking on behalf of the Asylum Workers' Association, states that the feeling on this question among those who are connected with institutions for the insane is pre-eminently one of strong objection to being left out of any scheme that may be proposed. For the Medico-Psychological Association, I can say positively that this was, and as far as I know, is now, the case. It was a threat of such an injustice that drove into action the Parliamentary Committee of the latter association more than ten years ago, when I happened to be its chairman. The steps then taken averted the danger, but apparently did not remove it entirely. In 1905 there arose the same risk of exclusion, for, in spite of the evidence tendered by Dr. Shuttleworth and Dr. White to the Select Committee, it was stated at almost the last moment, on excellent authority, that admission to the register would only be accorded to those mental nurses who had added a minimum of one year's training in a general hospital to the requisite training in the asylum. In the emergency, Dr. Outterson Wood, the then President of the Medico-Psychological Association, took energetic and successful action. He showed to those with whom the responsibility for such a decision rested that this proviso would debar, as well in *future* as in *presenti*, almost the whole female wing and the whole male wing of the large army of mental nurses. The result of this strong protest was that the proposed arrangement of having a separate portion of the register reserved for them was at once introduced.

An estimated number of 50,000 general nurses is mentioned in a former number of the JOURNAL as ready for entrance to the new register. At the present moment there are 15,000 men and women engaged in nursing the inmates of the institutions for the insane, which are regularly visited by the Lunacy Commissioners. This total does not include those who are employed in work-house wards, or who are engaged in nursing the insane in private houses. Numbers alone will forbid the injustice that will attach to exclusion from a register. This being so, the arrangement provided appears to accord with common sense, and it will have the further merit of obviating somewhat Pharisaical argument on respective rights to inclusion.—I am, etc.,

Ticehurst, Dec. 26th, 1908.

H. HAYES NEWINGTON.

SIR.—Other ladies than Mrs. Hadfield have been good enough to suggest that the reason of my opposition to the State registration of nurses is owing to the supposed (by them) result which they think would follow, that there would be a considerable drop in the funds of the London Hospital, because they imagine we should no longer be able to send out nurses to do private nursing at the end of two years.

Mrs. Hadfield is quite wrong. There is nothing in the bill which fixes any "time limit" to training, and it is almost too obvious for words that opportunity and teaching, and not time, is the essence of training. Thirty years at some hospitals would not train a nurse, never mind how good an examination she passed. We are quite content with the opinion of the hundreds of physicians and surgeons who employ our nurses every year. A two years' London Hospital trained nurse was good enough to be chosen to nurse His Majesty. We are quite satisfied, from experience, that our nurses are properly trained to undertake any work in two years, and the thousands of confidential reports we have at the hospital on this work establish this beyond dispute.

Even if this Registration Bill ever passes the House of Commons, which I do not believe it ever will, as opposition to it grows every day, and even if the Council were to decide that they would not admit on to the register any nurse who had not had, say three years' training, that would not affect the London Hospital in the smallest degree, as our nurses would not register. All the bill provides is that no nurse can call herself a "registered

nurse" who is not on the register of this Council. Does Mrs. Hadfield seriously suggest, in face of the reputation which the London Hospital has gained for turning out good nurses, that if our nurses wished to register the Council would say that the London Hospital was "not approved of as a training school" (see Section 12)? Registration may possibly help indifferent nurses to pose as good nurses, guaranteed by people who know nothing about them; but, in my opinion, for what it is worth (and Mrs. Hadfield and her friends will say, "Very little"), few of the best nurses will register.

Lord Crewe, speaking on the Registration Bill in the House of Lords, said: "If I were ill and required the services of a nurse, I should get one from a hospital or institution of standing, and should not inquire whether or not her name was on the register," and so would most thinking people. I cannot at the moment think of a better advertisement for the private nurses of the London Hospital than that there should be two sorts of nurses—"registered" and "London Hospital nurses"—the one guaranteed by people who know nothing about them, the other by those who know all about them, and can guarantee their skill, and, what is equally important, their suitability for the special service they may be called on to perform.

Mrs. Hadfield asks why matrons and nurses who are opposed to registration do not lift up their voices. She can hardly be aware of the deputation which went to Lord Crewe on the subject, nor of the memorandum against registration signed by 163 matrons of London and provincial hospitals, by 484 nurses (without any canvassing), and by a great number of the leading members of the medical profession.

We, who are opposed, do not ignore the bill, but these engaged in work are too busy to agitate, and it is not easy to agitate against something which is non-existent. It is, for instance, only quite recently that an anti-suffrage agitation has commenced. There will be plenty of time to make ourselves effectually heard when the bill gets within the region of possible passing. I see that all the Scottish training schools have met and seem opposed to the present bill, and that one society, which Lord Amthill (of course inadvertently) quoted as being in favour of it, have written by its secretary to say it is opposed.—I am, etc.,

SYDNEY HOLLAND,

Chairman, London Hospital.

December 22nd, 1908.

A HOSPITAL FOR MENTAL DISEASES.

SIR.—In a leading article in the JOURNAL of December 19th, 1908, dealing with Dr. Henry Maudsley's munificent gift to the London County Council, the following words appear:

"These, that is, individual attention and close personal treatment, which are all-important in the early stage of mental disorder, are impossible in the wards of large asylums, where patients in every stage are perforce herded together, with the result that those whose disease is of the acute form sooner or later take the colour of their surroundings."

Surely the writer of this article cannot be aware of the modern management of asylums, in which hospital wards are provided for the new cases; and to write of such as being "herded" with the chronic cases is, to say the least of it, inaccurate, though a stronger word might not be out of place.

There are other matters touched upon in the article which might easily form material for discussion; but these I pass aside, as my main object in writing this letter is to express the regret that the advocacy of so excellent a cause as the Maudsley Hospital should be marred by unnecessary and erroneous statements.—I am, etc.,

R. H. STEEN,

Medical Superintendent, City of London
Mental Hospital.

Dartford, Kent, Dec. 21st, 1908.

* * * We may remind our correspondent that Dr. Maudsley in the letter conveying his offer to the London County Council, which was published in the BRITISH MEDICAL JOURNAL of February 22nd, 1908, page 457, said, in enumerating the advantages of a hospital for mental diseases:

"It is hoped that in a small institution, with several medical and other attendants, the patient and apt application of individual treatment, mental and medical, would bring about

recoveries which might not take place in large asylums in which multitudes are congregated and such individual treatment is almost impracticable.

In the report of the Asylums Committee as to the London County Asylums on which we commented in the article referred to by Dr. Steen, the following passage occurs:

The most forcible argument for the provision of the hospital, from the point of view of the patient, lies, as it seems to us, in the fact that it will provide opportunity for individual treatment and close personal attention, which are all-important in the early stages of mental disorder. At the present time, in connexion with the more modern of the London County Council asylums, there are detached buildings which afford facilities for the classification of the patients and for the separate housing as far as the villa accommodation will permit, of those who are amenable to treatment. But apart from this, the only means of classification are found in the ordinary wards of the asylums.

The report further refers to the fact that "there will be in the hospital an entirely different atmosphere to that of the ordinary asylum, an atmosphere, as Dr. Maudsley has expressed it, of sanity as opposed to one of insanity." Our article, like the report of the Committee, dealt with the London County Council asylums. We do not know the exact atmosphere of the City of London Mental Hospital, near Dartford, but Dr. Steen would seem to have strangely misunderstood our article, or not to have read the documents on which it was founded.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following candidates have been approved at the examinations indicated:

PRELIMINARY SCIENCES: Mathematics and Physics.—H. Ball, Brasenose; R. R. Baxter, St. John's; R. Bonmure, Christ Church; A. W. Clements, Magdalen; R. H. Crane, Keble; H. C. Doynce, Trinity; V. T. Ellwood, Pembroke; D. M. Ely, Exeter; H. T. Evans, Jesus; C. G. Fanning, Exeter; A. G. Harper, Magdalen; S. J. Head, Lincoln; W. H. Jones, non-collegiate; W. V. A. Jones, non-collegiate; D. H. Jones, Jesus; O. P. Jones, Jesus; E. H. Kennard, Exeter; T. S. Nelson, University; R. W. Poulton, Balliol; L. K. Underhill, Jesus; C. A. Vileland, Balliol; J. West, Jesus; B. H. Wildon, Lincoln.

Chemistry.—W. Agar, Oriel; F. C. Baker, Balliol; H. Ball, Brasenose; R. R. Baxter, St. John's; W. G. V. Bloag, Keble; H. A. Boldero, Trinity; R. Bourmure, Christ Church; E. A. Bull, Jesus; F. E. Chavasse, Balliol; A. W. Clements, Magdalen; W. T. Collier, Balliol; R. H. Crane, Keble; K. M. Dyott, non-collegiate; V. T. Ellwood, Pembroke; H. T. Evans, Jesus; R. A. Fawcett, Oriel; A. E. Fisher, Balliol; J. F. M. Floyd, Queens; F. W. Haefliger, New; G. Harney, Magdalen; S. J. Essold, Lincoln; S. Jalland, Lincoln; O. P. Jones, Jesus; R. O. Langdon, Oriel; J. A. Liddell, Balliol; R. H. Johnson, B.A., Pemb.; I. W. Joynt, B.A., Emm.; A. Kennedy, B.A., Cai.; G. L. Keyner, B.A., Trin.; J. Peck, Trin.; Emu.; G. M. M. Emm.; H. H. Matthews, King's; G. O. Maw, Pemb.; G. W. Mitchell, B.A., Cai.; R. S. Morshead, B.A., Trin.; M. N. Perrin, Pemb.; C. H. G. Philip, B.A., Joh.; E. G. T. Poynder, Cai.; E. C. Rayner, B.A., Cai.; L. C. Rivett, Trin.; F. H. Robbins, Fawc.; F. G. Rose, B.A., Joh.; H. W. Scott, B.A., Cai.; A. S. Seabrooke, B.A., Christ's; F. T. Shackell, B.A., Pemb.; R. A. Sherman, Cai.; T. H. G. Shore, Joh.; G. Sparrow, B.A., Cai.; W. A. Stokes, B.A., Emm.; J. L. M. S. Cane, B.A., Trin.; J. F. Taylor, B.A., H. Selw.; G. S. Thomas, Down; F. S. Tinker, B.A., Pemb.; J. R. Waddy, Pemb.; C. B. Wainwright, B.A., Cai.; L. C. Walker, B.A., Christ's; F. W. Watkinson, Trin.; A. J. Wauze, B.A., Pemb.; L. M. W. Wauze, B.A., Pemb.; S. M. Wilcox, Trin.; R. W. Wilcox, B.A., Cai.; B. H. C. Wilson, Trin.; J. Winterbottom, King's.

THIRD M.B. (Part I).—W. B. Alcock, Trin. H.; L. A. P. Anderson, Emm.; V. A. Anderson, B.A., Cai.; F. A. P. Ayres, B.A., Trin.; E. B. Booth, B.A., King's; A. A. Cane, B.A., Trin.; E. G. S. Cane, B.A., Jes.; F. G. Chandler, B.A., Jes.; A. F. Conyn, B.A., Pemb.; K. Conyn, B.A., H. Selw.; R. F. P. Cory, B.A., Cai.; H. L. Duke, B.A., Cai.; H. G. Earle, B.A., Trin.; L. C. Rivett, Trin.; J. T. Frost, B.A., Sid. Suss.; G. G. Greaves, B.A., Emm.; A. C. Johnson, B.A., Down; F. I. M. Jupe, M.A., Down; T. H. Just, B.A., Trin.; W. Ledlie, M.A., Christ's; C. Mackenzie, Trin.; Emm.; W. G. Marsden, B.A., Emm.; E. H. Moore, B.A., Trin.; H. Moore, B.A., Trin.; B. Oliver, B.A., Trin.; W. P. Pigion, B.A., Christ's; H. B. Pope, B.A., Cai.; L. Powell, King's; J. E. Pulling, B.A., Christ's; R. A. Ransau, B.A., Cai.; E. A. Rayner, B.A., Cai.; W. F. Rhodes, B.A., H. Selw.; F. E. W. Rogers, B.A., Emm.; W. D. Ross, B.A., King's; S. H. Ronquette, B.A., King's; H. B. G. Russell, B.A., Sid. Suss.; I. V. Russell, B.A., Emm.; A. Sandison, B.A., Trin.; F. J. Thorne, B.A., Jes.; W. B. Topley, B.A., Joh.; J. B. A. Wignall, B.A., Cai.; N. S. Williams, B.A., Cai.; C. R. Wright, B.A., Christ's.

THIRD M.B. (Part II).—A. G. Atkinson, B.A., Trin.; G. G. Butler, B.A., Emm.; H. Chapelle, B.A., Joh.; J. F. Clennish, M.A., Cai.; A. H. Crook, B.A., Christ's; L. E. Dudgeon, B.A., Sid. Suss.; H. B. Elton, B.A., Cai.; A. G. D. Firth, B.A., Trin.; C. L. Forde, B.A., Cai.; G. A. F. Heyworth, B.A., Trin.; W. H. Hodkinson, B.A., Christ's; B. Hughes, M.A., H. Selw.; W. M. Jeffreys, B.A., Trin.; J. L. Joyce, B.A., King's; H. Lee, B.A., Cai.; J. B. Jole, B.A., Emm.; R. M. Moore, P. A., Joh.; F. Parsons, B.A., Cai.; R. F. Priestley, B.A., Cai.; C. Raymond, B.A., Cai.; E. N. Russell, B.A., Trin.; O. R. Smale, B.A., Cai.; A. E. Stangfield, B.A., Joh.; A. C. Sturdy, B.A., Pemb.; R. S. Suss., B.A., Sid. Suss.; B. A. Suss., B.A., Sid. Suss.; W. W. Treves, B.A., Cai.; R. M. Vick, B.A., Jes.; A. C. Warren, M.A., Emm.; T. N. Wood, B.A., Pemb.; A. E. M. Woolf, B.A., Emm.

An examination for the diploma in Tropical Medicine and Hygiene will commence on Wednesday, January 15th.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated:

M.D. in Medicine.—H. H. Bashford, London Hospital; Dorothy C. Hare, London (Royal Free Hospital); S. H. Hare, London (Royal Free Hospital); St. Thomas's Hospital; J. M. O'Meara, University College Hospital; W. M. Sadler (University Medical); University College Hospital; W. O. Sankey, St. Thomas's Hospital; W. L. Scott, University College Hospital; A. St. John, St. Bartholomew's Hospital; T. M. Tibbets, University of Birmingham; Ivy E. Woodward, London (Royal Free Hospital) School of Medicine for Women.

* Obtained the number of marks qualifying for the University Medal.

M.D. in Pathology.—O. C. Gruner (University Medical), University of Leeds.

M.D. in Midwifery and Diseases of Women.—F. Alcock, Guy's Hospital; D. H. de Souza, D.Sc., University College Hospital; R. A. Hendry, (University Medical, University of Liverpool); Ethel F. Iredell, B.A., London (Royal Free Hospital) School of Medicine for Women; C. A. L. Mayer, Guy's Hospital; A. Bandle, University College Hospital.

M.D. in State Medicine.—Barbara Tcharkovsky, B.Sc., London (Royal Free Hospital) School of Medicine for Women and University College.

M.D. in Tropical Medicine.—H. R. Nutt, St. Mary's Hospital and London School of Tropical Medicine; O. Marriott, Guy's Hospital and London School of Tropical Medicine.

M.S.—W. R. Battye, B.Sc., University College Hospital and St. Bartholomew's Hospital; A. J. Bixland, University College Hospital; C. A. Moore, University College Bristol and London Hospital; H. J. Nightingale (University Medical) St. Thomas's Hospital; H. B. Whitehouse, St. Thomas's Hospital and University of Birmingham.

* Obtained the number of marks qualifying for the University Medal.

UNIVERSITY OF LEEDS. FACULTY OF MEDICINE.

THE following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B. Part I.—W. T. Hessel, A. Riley, C. G. K. Sharpe, and A. E. Taylor.

Part II.—H. Vallow.

The degree of M.B., Ch.B. has been conferred on Mr. Vallow, and the diploma in Public Health awarded to Captain H. C. R. Hime, M.B., Ch.B. Victoria.

THE NEW IRISH NATIONAL UNIVERSITY.

At the first meeting of the Senate of the National University held last week, the Right Rev. William Walsh, D.D., Roman Catholic Archbishop of Dublin, was unanimously elected Chancellor.

UNIVERSITY OF DUBLIN.

At the close of the Michaelmas term on Saturday, December 19th, 1908, the Senate of Dublin University met at the Examination Hall, Trinity College, and duly installed the Right Hon. Viscount Iveagh, K.P., as Chancellor, in succession to the late Earl of Rosse.

The following degrees were conferred at the same meeting:

M.B., Ch.B., B.A.O.—R. J. Attridge, J. C. Baker, J. F. Clarke, G. Halpin, G. A. Jackson, N. P. Jewell, G. Knapp, G. McCreedy, G. A. Nicholson, T. Ryan, F. N. Smartt, H. V. Stanley, H. S. Sugars, A. S. Winder.

M.D.—J. J. Abraham, R. Bailey, H. English, G. Halpin, D. F. Hunter, G. F. W. Leech.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.

Dr. F. W. Mott, F.R.S., senior physician to Charing Cross Hospital, presided at the prize distribution on December 18th, 1908. The report presented by the Dean, Mr. F. C. Wallis, F.R.C.S., referred with regret to Lord Knorr's resignation of the chairmanship of the hospital and to the death of Dr. Montague Murray. Dr. William Hunter had succeeded to the post of physician, and Dr. R. C. Jevesbury had been appointed assistant physician. Dr. Routh had been succeeded as Chairman of the School Committee by Dr. F. W. Mott. Owing to the able management of the secretaries of the Students' Club, particularly Mr. D. P. Williams, the long-wanted alterations in the club-room had been carried out. The prizes were presented by Mr. J. H. Morgan, consulting surgeon to the hospital. The Epsom Scholarship was won by Mr. A. M. Jones, the Huxley Scholarship by Mr. E. A. Sutton, the Governors' Clinical Gold Medal by Mr. T. W. Jones, and the Universities Scholarships by Mr. C. W. Shepherd and Mr. W. R. Thomas.

Mr. Morgan afterwards delivered an address to the students and their friends, expressing his congratulations on the successes which had been won in the examinations during the year and on the success of the Students' Club. He discussed the value of a small hospital as compared with a large hospital from the point of view of medical training. He said that he was not infrequently asked by parents to what school they should send their sons, and he found that it was the general impression that the larger the hospital the better the opportunity for learning. That he ventured to doubt. Six cases well studied and carefully noted were of more instructive value than fifty of which the student could have only a cursory knowledge. It was not the rare and obscure cases that they would have to deal with in private practice; what would serve them best was an intimate acquaintance with the more common types of disease. Once students had entered the wards or out-patient rooms as clerks or dressers they would largely have to instruct themselves. Careful note-taking was valuable, because it not only induced the habit of accurate observation, but it also impressed a case upon the mind in a way that nothing else could. It was not his fortune to gain a prize for a series of notes of cases, and though it was many years ago, every case was vividly recalled to his mind when he read the notes. If they had any facility for drawing, they should cultivate and make use of it in their notes—there was nothing which gave a better power of estimating size and proportion so useful alike to the physician and the surgeon. It used to be thought necessary for any one who sought to follow the higher lines of medical work to attend at a German university or school, but so good and so practical was the teaching, and so great the experience to be gained at home, that in general it was better not to go abroad, except, perhaps, for special work.

LONDON SCHOOL OF TROPICAL MEDICINE.

The following gentlemen have been approved at the twenty-eighth sessional examination:

* Captain R. R. Dutton, I.M.S., * Captain R. E. Stanger Leathes, I.M.S., * J. Macgregor Smith, * W. H. Thrasher, * H. B. Kent, * Captain H. C. Brown, I.M.S., * T. H. Sufter, * H. S. Coghill, A. Copland, * S. R. Shrivastkar, * J. G. Copland, A. G. Payne, P. Stallard, S. A. McClintock, * P. F. Foran, * S. C. G. Fox, * O. G. F. Luhn, * T. H. Drayton, Miss E. Shepherd, * W. C. Hossack, * Captain A. Spittler, I.M.S., A. Tröndle, * S. MacLaine, * A. Browne, O. Marriott, * E. Slack.

* With distinction.

† Colonial Service.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

Surgery.—* D. F. Dobson, J. M. Fiske, * W. N. Pickles, * A. F. Reardon.
Medicine.—H. W. B. Dauner, * D. F. Dobson, * J. M. Fiske, * J. S. R. Lewis, * H. A. Parker, * W. N. Pickles, S. H. Watton, * R. P. Wylie.
Forensic Medicine.—A. H. C. Dawes, D. F. Dobson, J. M. Fiske, W. N. Pickles, H. T. Roberts.
Midwifery.—D. F. Dobson, J. M. Fiske, J. B. Moore, W. N. Pickles, G. G. Rigby, J. W. Williams.

Section I.

† Section II.

The diploma of the Society has been granted to Messrs. D. F. Dobson, H. A. Parker, and A. F. Reardon.

Contract Practice.

FRIENDLY SOCIETIES AND MEDICAL CONTRACT RATES.

SIR.—Letters appear periodically in your columns referring to the remuneration received by club doctors, but nothing is done to remedy the grievance.

Perhaps the following facts about the financial position of the leading Friendly Societies may interest those who are paid by the same societies 4s. per annum for adults and 2s. per annum for juveniles.

	Capital.	£	s.	d.
Manchester Unity of Oddfellows	...	13,822,043	6	11
Ancient Order of Foresters	...	7,636,269	11	5
National Deposit Friendly Society	...	874,820	17	4
Rational Associated Friendly Society	...	600,000	0	0
Grand United Order of Oddfellows	...	1,446,063	17	0
Independent Order of Rechabites	...	2,018,635	0	0
Loyal Order of Ancient Shepherds, Ashton	...	1,024,827	0	0
Unity	...	310,000	0	0
United Ancient Order of Druids	...	400,000	0	0
National United Order of Oddfellows	...	188,350	0	0
Order of Druids

These figures refer to 1908, and show that ten societies have between them a total capital of over twenty-eight million pounds. From the paper in which this statement appeared I quote the following:

The registered friendly society usually provides a medical benefit, by which skilled medical attendance and medicine is secured to the members at the same cost as in a collecting (insurance) company is paid for the collection of the contributions.

From this it seems that our skilled services are valued at the same rate as the unskilled work of a collector of pence.

Some years ago, when I held an appointment as colliery surgeon, my assistant was once invited to "have a drink" with a club patient. Upon his declining the offer, this was what the collier said: "Ah! you're too proud to drink with me, but you're nowt but my servant, my b. servant"; and that, I think, exactly describes the position of affairs.

We, who have spent much time and money in getting qualified, are practically in a degrading bondage to the very men who themselves are always insisting on a fair wage, and we tamely submit, instead of taking a leaf out of their book, and by united action forcing them to come to our terms.

Is it not possible to get every medical man to promise not to accept club work excepting upon such terms as may be agreed to by a central committee? Surely those who do not hold club appointments could be brought to see that indirectly they would also benefit by supporting such a resolution, even if no higher motive would influence them.

So far as I can ascertain, the only reason why all club doctors do not strike for adequate pay is that they fear their colleagues or opponents would step in and take their appointments, which implies that our standard of conduct is considerably lower than that of the working man.

Is this really so? I doubt it, and believe that the majority of our members would be loyal.

Could not the experiment be tried—say in one Division—of sending circulars or postcards to every medical man in the district to ascertain how many would give their support?—I am, etc.,

South Brent.

F. W. STYLE.

The Services.

PAY OF LIEUTENANT-COLONELS IN THE R.A.M.C. (TERRITORIAL FORCE).

WE are informed that the action of the War Office expressed in the letter of Sir E. W. D. Ward of November 17th, 1908, published in this column last week (p. 1898), is to be accounted for by the fact that in the Regular Army a medical officer above the rank of major never holds a regimental appointment. It was promised that a volunteer transferring to the Territorial Force should not lose his rank, a Lieutenant-colonel R.A.M.C.(T.F.) consequently retains that rank in the service, but, as long as he serves regimentally, is held to be entitled to receive only the pay and allowances of a major.

HIGHLAND DIVISION NURSING SERVICE.

A MEETING of the Highland Division Nursing Service Committee of the Territorial Force was held in Aberdeen last week to consider details regarding the establishment of a nursing service in the North of Scotland, with a centre in Aberdeen. Matrons, Sisters, and nurses were enrolled, so that the service for the Highland Division is now complete. Miss MacNaughton, Aberdeen, is Organising Matron.

Medico-Legal.

UNIDENTIFIED BODIES.

IN each of two cases which occupied the time of the jury in the City of London on December 12th the identity of the deceased was a matter of some doubt. In the one case it was not determined at all; in the other it was eventually settled by the clothing. This case was one of drowning; when the body was removed from the water the features of the deceased could have been identified by any one familiar with them, but by the time the body was claimed they were unrecognizable. As a result the jury suggested to the coroner that he should communicate with the authorities and urge the provision of a proper refrigerating apparatus, so that bodies might be preserved unchanged for any period necessary. This suggestion is clearly to the point, because there must be numerous cases in which identification of a dead body is of immense importance not only to individuals but to the public. It is somewhat curious, however, that there should be need for such advocacy at the present date, for the value of refrigerators in connexion with public mortuaries was recognized not only by medical men but by the Legislature nearly twenty years ago. A clause on the subject may be found in the Public Health Act (London) of 1891, Section 93, providing for the fitting up of one or more suitable buildings to which dead bodies found in London and not identified, together with any clothing and other articles found with or on them, might be removed and preserved with a view to their ultimate identification. Furthermore, the point is one to which, we believe, Dr. Wallo and other coroners have repeatedly drawn attention. The delay, therefore, on the part of the authorities to take advantage of the power conferred upon them by the Act is not readily comprehensible. Another arrangement, the drawbacks of which are evident on the surface, is that by which mortuaries and coroners' courts are sometimes placed at a considerable distance apart; Southwark is an instance in point. The necessity to attend an inquest either as a jurymen or as a witness is a sufficient infliction in itself without the addition of unnecessary waste of time, such as that which is inevitable when juries have to walk considerable distances to view bodies.

THE PECULIAR PEOPLE.

A VERDICT of manslaughter was returned at a coroner's inquest at Canning Town on December 19th, 1908, against the father and mother of a child which had died of measles and pneumonia. The medical evidence showed that death had been accelerated by neglect to obtain medical assistance. The parents belonged to the sect known as the "Peculiar People," and in conformity with their beliefs sought no medical assistance. The mother testified that she had belonged to the sect for nearly thirty years. Of her eleven children, nine were living. Both parents were committed for trial on the coroner's warrant.

VALUE OF A PRACTICE.

JUNIOR.—The value of a practice under such circumstances as those stated would be very considerably depreciated, but to give on such data even an approximate value would be quite impossible.

PARTNERSHIP ACCOUNTS.

ACCOUNT asks if it is usual for the incoming partner of a firm to have access to the ledger used before his time. He also wishes to know whether, in the case of a patient paying

money to the new firm, it should be applied to the settlement of their account, or whether the old firm has a prior claim to it for an old account still unsettled.

* * It is usual for an incoming partner to have access to the ledger used before his time, when necessary for the purpose of carrying on the common business. In the case of patients running long accounts, it might often be necessary to look up their financial record. He has no claim to have access for any other purpose. The payment of bills should be in the order in which they were contracted. When patients of an old firm continue to employ the new, the accounts of the old should be paid before those of the new, unless the former have become irrecoverable under the Statutes of Limitation.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

RELATIONS OF MEDICAL MEN TO PATENT MEDICINES.

OUR opinion is asked on the following matter: X, has a patient who, when living in another town, was given by Dr. Z, a mixture also is still taking. As it appears to suit her, X wishes her to continue it if its ingredients are compatible with his other treatment. He has therefore asked Z, what it contains, but has been told by Z, that, while willing to supply the medicine to the patient whenever she requires it, he cannot disclose its contents because the formula was given him a year or two ago by an American who is about to bring out the mixture as a patent medicine.

* * We assume that X, has no interest whatever in the proposed patent medicine, but only considers himself in some way bound in honour not to disclose the formula he received from the American. Nevertheless, it is to be regretted that he should have used in his practice a remedy which is subject to such restrictions. It is a recognized rule that medical practitioners should not use secret remedies, and should not refuse to disclose the nature of any treatment they employ, therefore Z, cannot consistently with this rule continue to supply this medicine to his patients.

RIVAL CLAIMS TO A PATIENT.

B. AND H. are neighbouring practitioners in a small town, and are on friendly terms. M. is assistant to H. In the temporary absence of H., M. asked B. to see a boy with a crushed hand, and it was agreed that the boy should be sent to the hospital; and M. also asked B. to operate, he giving the anæsthetic. B. did so, but afterwards "claimed the case." M. is chagrined at this, and asks whether it is customary, or what was the proper procedure on the part of B. and M.

* * We are not quite clear what "claiming the case" means, but we should think it usual for the surgeon who performed the operation to continue the after-treatment. The notion that the surgeon's concern with the case ends with stitching up the wound seems out of date, as ultimate success so often depends upon subsequent attention to details.

THE TITLE OF "SENIOR."

ANTIPODES asks which of two practitioners has the right to call himself the senior—D., who practised for a short time in a time, but went away for a time; or T., who started practice two years before D. returned. The interval between D.'s going and returning is stated to have been some years.

* * We are not aware that it is customary in this country for practitioners to adopt the title or to style themselves "Senior Practitioner" in the town or village in which they live, and we should certainly deprecate its introduction as being invidious and exceedingly difficult to define. If, for example, it were taken to mean the man longest in practice in the place, it might so happen that he would be junior in age and in the date of his professional qualifications to his colleagues; but we do not think any other basis for the classification would be more satisfactory, although it is possible that a better solution has occurred to our antipodean colleagues. As D. seems to have practised in the town long before T., and on the whole for a longer period, he would seem to have most claim to call himself "senior."

Obituary.

GRIFFITH GRIFFITHS. L.R.C.P.EDIN.,
M.R.C.S.ENG., J.P.,
PONTARDAW.

We regret to announce the death of Dr. Griffith Griffiths, J.P., of Pontardawe, which occurred at his residence on December 17th, 1908, after a long illness. Dr. Griffiths was born in January, 1840, at Alltven, Swansea Valley, the son of an independent minister—the Rev. Philip Griffiths, a man of marked individuality and the possessor of great influence in his sphere and time. After several years spent at the village school he went to the Normal College, Swansea, at that time the most noted secondary school in Wales, whose head master, Dr. Evan Davies, admittedly, apart from the success of the school, did more towards educational reform in Wales than any other man of his time. From school, as was then the custom, Griffiths was apprenticed to the late Mr. John Paddon, M.B.Lond., at Swansea, who at the time was Surgeon to Vivian's copper works, and conducted also a large private practice. In 1859 Griffiths entered at University College Hospital, and whilst there obtained the gold medal in *materia medica* in 1861, and the first silver medal in midwifery in 1862. In 1864 he became M.R.C.S.Eng. and shortly afterwards L.R.C.P.EDIN. At University College he had as fellow student Sir John Williams, and the strong friendship which then sprang up was known to have lasted throughout subsequent years. Before leaving London Griffiths served for a short time as house-physician to the Brompton Hospital for Consumption; he returned to Wales and settled in practice in Pontardawe, and soon after through a death vacancy succeeded to all the district public appointments as well as to an extensive private practice. He was a neat and pains-taking surgeon and was much in request as an accoucheur. From his early manhood he was troubled more or less with winter cough; latterly this became aggravated and the usual complications supervened. From these he died on December 17th, leaving a widow and an only child, now married to Dr. O. Evans, who for some years had done much of his professional work.

A few years ago Dr. Griffiths was made a Magistrate for Glamorganshire, and until his health failed took a keen interest in petty sessional work. He was always very good company, and had a memory well stored with folklore and Welsh literature. In his younger days he was very fond of music, and devoted much time and labour to Welsh choir singing; it was the pride of his life to talk of the gold watch and chain presented to him by his father's congregation for his successful efforts with the chapel choir. At the Pontardawe Board of Guardians on December 17th, 1908, Mr. Herbert Lloyd feelingly referred to the death of Dr. Griffiths, and moved a vote of condolence with the family; the vote was adopted in silence.

We regret to have to record the death, at Beyrout, on November 22nd, 1908, of JOHN WORTABET, M.D., in the 82nd year of his age. He was for many years Professor of Anatomy at the Medical College and Physician to the Hospital of the Knights of St. John in that city. He published some years ago an Arabic version of *Gray's Anatomy* for medical students in Syria and Egypt. He was also the author of several medical works in that language and the writer of a number of articles on plague, leprosy, and allied subjects in the British medical magazines. Dr. Wortabet was the recipient of the Order of the Medjidieh and of the Knights of St. John in recognition of his professional services. His death is mourned by three daughters and three sons, who survive him, two of the latter being members of the profession. His loss will be felt also by a large circle of friends, amongst whom are many of his former pupils.

Dr. JUSTIN LEMAISTRE, who died recently, was for many years Professor of Anatomy in the Medical School of Limoges, and a leading practitioner of that town. He was *interne* of the Paris hospitals, and took the degree of Doctor of Medicine in 1875. He was the author of writings on external oesophagotomy in children, peritonitis abscess, and on the air of Limoges and its porcelain factories. He was the first to describe *periliche*, a con-

tagious disease of the mouth occurring in children caused by the *Streptococcus plicatilis*, which lives in wells, and is transmitted to the lips by unclean drinking vessels. This discovery was published in 1886.

DEPUTY INSPECTOR-GENERAL WILLIAM SPENCER LIGHT-FOOT, R.N. (retired), died on December 14th, 1908. His commissions were thus dated: Surgeon, March 31st, 1880; Staff Surgeon, March 31st, 1892; Fleet Surgeon, March 31st, 1896; and Deputy-Inspector-General of Hospitals and Fleets on retirement from the service, June 9th, 1904. He was surgeon of the *Decoy* at the bombardment of the Alexandria Forts in 1882, receiving a medal with clasp and the Khedive's bronze star; he was also in the operations near Suakin, in the Eastern Soudan, in 1884, receiving an additional clasp.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Bela Weiss, of Vienna, sometime editor of the *Wiener medizinische Presse*, who had earned a high reputation by his writings on general subjects, aged 70; Dr. Elloi Dudon, Deputy Professor of Anatomy in the Medical Faculty of Bordeaux, and a surgeon of considerable reputation; Dr. Felizet, Surgeon to the Paris Hospitals and General Secretary of the Paris Surgical Society; Dr. Joffroy, Professor of Clinical Mental Pathology and Diseases of the Encephalon at the Paris Medical Faculty; Dr. Benjamin Anger, formerly Surgeon to the Paris Hospitals and *professeur agrégé* of the Faculty of Medicine; Dr. Alejandro San Martín y Satrustegui, Professor of Clinical Surgery in the Central University, Madrid; Dr. Vincenzo Brigidi, formerly Professor of Morbid Anatomy in the University of Genoa, and author of numerous monographs on pathological subjects, aged 70; Dr. Theodore Jules Ernest Hamy, Professor of Anthropology at the Paris Museum of National History, Member of the Paris Academy of Medicine, and author of a treatise on human pathology and of numerous works on anthropology, aged 66; Dr. Georg von Rindfleisch, Professor of Pathology in the University of Wurzburg, author of a *Textbook of Morbid Histology*, *Elements of Pathology*, and smaller works on tuberculosis and scrofulosis, in his 72nd year; Dr. Ferdinand Jouvénel, Director of the Sanatorium at Montigny en Ostrevant, founded a few years ago under the auspices of the *Ligue du Nord contre la Tuberculose*, a post for which he was selected by Professor Calmette; Dr. Andrew J. McCosh, a prominent surgeon of New York, aged 50; and Professor J. Schnadel, Director of the First Ophthalmological Clinic of the University of Vienna, aged 66.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

EXAMINATION OF FOREIGN MEAT.

REGULATIONS made by the Local Government Board under the Public Health (Regulations as to Food) Act, 1907, subjecting certain kinds of imported meat intended for consumption in this country to more stringent examination, came into force on January 1st. The Board, being very properly desirous of securing uniformity in the administration of the regulations at the various ports of entry, has issued a circular to all the port sanitary authorities and certain borough and district councils containing advice as to the manner of procedure to be adopted under particular circumstances. Imported pork in portions less than the entire carcass may now be detained by the Customs officer for examination by the medical officer of health unless the package containing the consignments is accompanied by a certificate from a competent authority in the place of origin that the pig at the time of slaughter was free from disease, and that the dressing, preparing, and packing of the carcass has been carried out properly and with a view to the prevention of danger to the public health if the meat is used as an article of food. A schedule of official certificates which will be accepted by the Board is in course of preparation. Where the presence of tuberculosis is discovered in pigs imported whole the medical officer of health is advised to condemn the whole carcass as unfit for human consumption in accordance with the recommendation of the Royal Commission on Tuberculosis, 1896. It is very certain that the work of the sanitary officials concerned in the administration of these regulations will be very great, so that it is not at all surprising to find that the Local Government Board anticipate the necessity for appointing assistant officers, who, it is needless to say, should be specially trained for the work they will be required to perform.

Hospitals and Asylums.

JAMES MURRAY'S ROYAL ASYLUM, PERTH.

The annual report of the committee and the medical superintendent, Dr. A. R. Ure, of this private asylum, contains the medical superintendent's report for the year ending March 31st, 1908, and the statistical tables for the year 1907. These latter show that, excluding voluntary boarders, there were 123 patients in the asylum on January 1st, 1907, and 122 on the last day of the year. The total cases under treatment during the year numbered 158, and the average number daily resident 124.09. These numbers show slight falls on those of the two previous years. During the year 35 were admitted, of whom 28 were first and 7 not-first admissions. Of the total admissions, in 3 the attacks were first attacks within three, and in 9 more within twelve months of admission; in 9 not-first attacks within twelve months of admission; in 13, whether first attacks or not, of more than twelve months' duration on admission; and in 1 case of congenital origin. The admissions were classified according to the forms of mental disorder into: Mania of all kinds, 13; melancholia of all kinds, 12; dementia, 2; delusional insanity, 1; confusional insanity, 2; and circular insanity and congenital mental defect, 1 each. The probable etiological factors were assigned in the following numbers: Alcohol in 5, syphilis in 2, the climacteric in 6, previous attacks in 13, and mental strain and worry in 5. An insane heredity was ascertained in 18, a neurotic heredity in 12, and an alcoholic heredity in 9. During the year 11 were discharged as recovered, giving a recovery rate in the admissions of 31.43 per cent., as compared with the average for the decade of 34.03 per cent.; 14 as relieved, and 1 as not improved. During the year 10 died, giving a death-rate on the average numbers resident of 8.01 per cent., as compared with the average of 6.08 per cent. for the decade. The deaths are returned as being due in 3 to influenza, and the remainder in single numbers to general paralysis, valvular heart disease, chronic alcoholism, pneumonia, pulmonary consumption, greyness of lung, and cold on admission. In the last-mentioned case the patient was suffering from iodine poisoning on admission. The admirable condition and management of this asylum is commented upon in highly favourable terms in the report of the Lunacy Commissioners for Scotland.

INVERNESS DISTRICT ASYLUM.

From the annual report of Dr. R. B. Campbell, the medical superintendent of the Inverness District Asylum, for the twelve months ending May 15th, 1908, we see that on May 16th, 1907, there were 572 patients on the register, and that on May 15th, 1908, there were 652. The total cases under treatment during the year numbered 835, and the average number daily resident 662. During the year 163 were admitted, of whom 116 were first and 47 not-first admissions. The readmissions formed 28 per cent. of the admissions, but this apparently high readmission-rate was partly accountable to the fact that constant effort is made to board with suitable guardians quiet and chronic cases, and that though the majority of these do well outside the asylum, some break down and have to be readmitted, thus factitiously swelling the readmission-rate. Of the total admissions 42, or 25 per cent., were in average bodily health and condition, the remainder being either in indifferent or weak and exhausted condition. In 73 the attacks were first attacks within three and in 22 more within twelve months of admission; in 47 not-first attacks within twelve months of admission; in 9 whether first attacks or not, of more than twelve months' duration on admission; and the remaining 12 were congenital cases. They were classified according to the forms of mental disorder into: Mania of all kinds, 75; melancholia of all kinds, 56; secondary dementia, 18; general paralysis and acquired epilepsy, 1 each; and cases of congenital or infantile defect, 12. As to the principal probable etiological factors in the admissions, alcohol was assigned in 16, or 9 per cent., syphilis in 1, dementia in 44, and "heredity" cases in 51. Hereditary influences were ascertained in 38, or 23.3 per cent., and, as already stated, congenital defect existed in 12. During the year 62 were discharged as recovered, giving a recovery rate on the admissions of 38 per cent.; 17 as relieved and 19 as not improved. The 17 discharged as relieved were harmless patients, incapable of further improvement in the asylum, and were handed over to their relatives to be boarded out with suitable guardians, and the 19 not improved 31 cases sent to the lunatic wards in the Long Island poorhouse, licensed by the Commissioners in the autumn of 1907 for the reception of chronic insane patients who did not require asylum treatment, but who were unsuitable for family care. During the year also 55 died, giving a death-rate on the average numbers resident of 8.3 per cent. The deaths were due in 15 to cerebro-spinal diseases, with only 3 from general paralysis; in 31 to chest diseases, including 11 deaths from pulmonary consumption; or 20 per cent. of the total deaths—and 14 from acute lobar pneumonia; in 7 to abdominal diseases; in 1 to sarcoma of skull and in 1 to asphyxia, the patient, not previously suspected of being suicidal and convalescent at the time, drowning himself in Beaulieu Firth. The asylum was visited by influenza, which was followed by pneumonia in many cases, but no other zymotic diseases appear to have attacked the patients.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL CHANGE OF ADDRESS.

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL have been removed to 429, Strand.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Articulate, London*. The telegraphic address of the MANAGER of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National):—

EDITOR,

2631, Gerrard.

GENERAL SECRETARY AND MANAGER,

2630, Gerrard.

MEDICAL SECRETARY, 2634, Gerrard.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Manager, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents in the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "Enquirer," and so on. By attention to this request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

ENDEMIC MALARIA?

ANOPHELINE writes: With a view to ascertaining the existence or otherwise of endemic malaria in a locality, 246 native children under 10 years of age were examined in November for enlargement of the spleen, and in 18 instances (roughly 7 per cent.) it was found to be appreciably enlarged. The vast majority of the children were resident in the locality for from four to six years, but were born elsewhere in places which were probably malarious. Mosquitoes exist in the locality in question, but the classes have not been differentiated. The entire European population do not spend more than a year in the locality and come from places where malaria is endemic. Attacks of malarial fever are very common amongst them in the proportion of 500 cases per 1,000 of population annually for the last seven years. The diagnosis has been verified microscopically in about 25 per cent. of these cases, one smear of blood only being, as a rule, examined before the administration of quinine. The climate favours the occurrence of chill; the thermometer being generally about 80° F. in the shade with an annual range of from 72° F. to 96° F., so that slight physical exertion causes free diaphoresis. High winds are common and these acting on the sweating skin cause chill. The question at issue is—Is malaria endemic in the locality and, if so, what would best describe its degree of prevalence—slightly, distinctly, very?

ANSWERS.

TREATMENT OF TAPEWORM IN CHILDHOOD.

MR. FREDERICK POWELL, Director, The Wellcome Chemical Research Laboratories writes: In the issue of the BRITISH MEDICAL JOURNAL of December 19th, 1908, p. 1948, I have observed a paragraph respecting the "treatment of tapeworm in childhood." We have recently been interested in an investigation of the constituents of pumpkin seeds, which, as you may know, are recognized by the United States Pharmacopœia under the title of "Pepo," and have long been regarded as one of the safest and most efficient vermifuges. Although this action has been attributed to the fatty oil expressed from the seeds, it has not yet been definitely established. It would be of considerable interest from a scientific as well as a practical point of view, to obtain some confirmation of the activity of this oil for the purpose indicated, and if your correspondent would like to try it, I should be very glad to supply him with the requisite quantity without cost. The oil is bland, not unpleasant to the taste, and if it should not prove effective it can do no harm to the patient.

TREATMENT OF FOLLICULAR STOMATITIS.

W. G. writes: If "M. W." will try touching each spot as soon as the slightest soreness is noticed with a small crystal of copper sulphate, and repeating once or twice (during the next day, I think he will find the ulcers arrested. The patient should avoid all uncooked vegetables and fruit whenever there is the least tendency to stomatitis, and a course of soda and rhubarb is about the best preventive.

RINGWORM OF THE SCALP.

H. H. writes: If "H. S. B." (December 26th, 1908) will paint the infected areas with tincture or liniment of iodine daily, after shaving the head, he will get rid of the trouble in a few weeks.

DR. WALTER GRIPPER (Wallington) writes: I have unfortunately had a long experience in an institution. Of course, where strong remedies such as croton oil have been used recently, or any irritation remains, it is somewhat risky to expose to the π rays, but I have on occasion had the patches themselves protected and the rest of the scalp depilated, so as to obviate any spreading, and then attacked each patch by careful needling with croton oil or epilating by electrolysis; the latter is somewhat painful for the moment, and should not be tried on large patches where a possible permanent alopecia would be much noticed. On the detection of a new case I now never attempt any remedies, but have the whole or such part of the scalp as is necessary exposed to the π rays, and find the time occupied in a cure lessened by one quarter at the least.

ADMINISTRATION OF DIPHTHERIA ANTITOXIN BY THE MOUTH.

R. G. H. writes: In answer to your correspondent's inquiries about the administration of diphtheria antitoxin by the mouth, I would strongly advise them to give the method a trial. With the exception of cases in which repeated vomiting is a prominent symptom, and which would make the retention of the antitoxin doubtful, I almost invariably give it in that way. In my experience it acts just as rapidly and certainly; it causes no gastric symptoms, it can be given at any time by the friends, and it avoids the disagreeable necessity of performing a painful little operation on a sickly child.

W. M. writes: I have always administered antitoxins by the mouth with satisfactory results. In diphtheria the improvement seems more rapid than in other cases where serum is given. The fact that the serum comes in contact with the direct seat of the infection seems to aid in the elimination of the virus from its stronghold. Quite recently I used the serum in two cases of diphtheria. The effect was marvellous. In one case the membrane dissolved rapidly, and in two days had disappeared; in the other not so quickly, but each day the membrane became thinner and less defined, until, in a week's time, it was gone, leaving the surrounding area clean and healthy. I had similar good results in septicaemia (puerperal), the temperature declining after the first administration. Although other measures were used and continued when giving the serum, the results obtained were directly noticeable after giving the serum by the mouth. I am convinced that this method is quite as satisfactory and, of course, much less troublesome and objectionable to the patient than the hypodermic method, and therefore my intention is to continue it. Some may contend that this method is not scientific, that the active properties of the serum may become destroyed in alimentary canal; possibly there may be some truth in this, but it is not all true, as the results attending its oral administration are sufficiently convincing to me.

M.O.H. (Hants) writes: "For the last few years" I have made it my practice always to administer antitoxin by the mouth, excepting in very urgent cases with unqualified success. Two years ago I had an epidemic to treat, and on this occasion administered over three hundred 2,000-unit doses without a failure.

LETTERS, NOTES, ETC.

NOTIFICATION OF BIRTHS ACT.

ALDERMAN J. C. MCWALTER, M.D. (Dux), F.F.P. and S.G. (19, North Earl Street, Dublin), writes: In the Corporation of Dublin are just now considering the adoption of the Notification of Births Act, any practitioner who may object should at once lay his views before that body.

A DISCLAIMER.

DR. A. E. NAISH (Sheffield) writes: My attention has been called to an advertisement by the West Surrey Central Dairy Company stating that I have demonstrated the superiority of English dried milk over fresh cow's milk for the feeding of infants. This statement is not only unauthorized but wholly incorrect and misleading.

MEDICAL INSPECTION OF SCHOOLS.

ISOLATED writes: In the distribution of these appointments I am sure there must be many medical men who, like myself, think they have been treated very unfairly. Within three miles of my house are no less than seven village schools, three of them within a mile, in order to reach which the medical men appointed have to travel over between five and eight miles of bleak and uninhabited country. I am the senior medical practitioner in the district, and my claims have been entirely ignored. Their intrinsic value at a shilling a head is not worth considering, but there are likely to be more serious and far-reaching consequences.

A "PERNICIOUS" ENEMA.

THE *St. Mary's Hospital Gazette* tells a story of some one who had made a complaint against the hospital that a relative had been killed by a "pernicious" enema. This was the interpretation of the diagnosis "pernicious anaemia" on the board by the patient's bedside.

TOOTHBRUSH BRISTLES AND APPENDICITIS.

MR. CORNELIUS A. GRIFFITHS, F.R.C.S. (Cardiff), writes: Three years ago I found a toothbrush bristle in the appendix of a girl aged 10 years, which I removed for recurrent attacks of pain. With the exception of numberless faecal "concretions" of varying degrees of density, this is the only "foreign body" I have found in an appendix, although I once found a living threadworm in the appendix of a man, which was amongst the contents of a hernial sac. I was operating in this case, however, for hernia and not appendicitis.

"THE BONE MARROW."

DR. W. E. CARNEGIE (Edinburgh) writes: In connexion with your kind review of my book on the bone marrow (*JOURNAL*, November 28th, 1908, p. 1616), may I venture to point out the following typographical error which occurs in it? In the sentence, "Dr. Dickson affirms that phagocytic cells are produced from the proliferating epithelium of the capillary wall," for "epithelium," read "endothelium." The review also states that "in Plate XII are given some excellent schematic representations of the development of the small lymphocyte into the adult polymorphonuclear cells and of the megakaryoblast into the erythrocytes, etc." Unfortunately this statement, as it stands, gives an erroneous impression of the views expressed with regard to the development of these cells, as some of the schemes in this plate, to which reference is thus made, were drawn up to represent the views of other writers; and from these my own deductions, given in the accompanying text, differ very materially in certain points.

THE MARRIAGE OF FIRST COUSINS.

DR. ARTHUR TOWN WHITE (Leightonstone) writes: Your interesting article on the above subject reminds me that some years ago a young man—now holding a high colonial appointment—consulted me as to whether it would be advisable for him to marry his first cousin. My answer was, No; given on the following grounds: (1) Every family has some slight defect in some one or other direction—it may be a slight defect in sight or hearing or mental capacity, so slight that it does not show, but it is there; in the event of cousins marrying the children would get a double dose, and then what in the parents would not be noticed becomes in the offspring a serious defect. (2) I have never in my life come across a family of five or six children whose parents were first cousins where all the children were good specimens of the race. The most common defect in my experience is blindness. It may be unusual, but I have never come across a person born blind whose parents were not cousins. If cousins marry they may have one or two healthy children, but I am absolutely convinced they will not go on to five or six without some very serious defect appearing in one or other of the children. The most common causes of defective children are, first and most important, taking drugs to procure abortion in the early months of pregnancy; secondly, alcoholism; thirdly, consanguineous marriages; fourthly, syphilis. Starvation, tuberculosis, etc., do not in my experience produce physical defects in children. With regard to consanguineous marriages amongst savage races, we cannot compare them in any way with European; mental and physical defects are less common amongst natives, who lead healthy lives, and when the law of the "survival of the fittest" has not been interfered with; there are therefore in them no family defects to be reproduced, and a marriage between cousins has no bad influence on their children. What I maintain is, that, eliminate the four above causes of defect in children, even if the parents are tuberculous, starved, overworked, etc., if the children are brought up with care and properly treated, there is no reason why they should show any defect at any time; with regard to the offspring of tuberculous parents, unusual care would be necessary. But whatever care you take of the children whose parents come under the four headings above mentioned, a very great percentage of them will be defective mentally or physically; I should say quite 40 per cent.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, W.C., later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

A Clinical Lecture

ABDOMINAL EMERGENCIES.

DELIVERED AT THE ROYAL INFIRMARY,
SHEFFIELD.

By SINCLAIR WHITE, M.Ch., F.R.C.S.,

SENIOR SURGEON TO THE INFIRMARY; LECTURER ON SURGERY,
SHEFFIELD UNIVERSITY.

It would be impossible in a single lecture to review, however briefly, the entire field of abdominal emergencies, and I shall therefore confine my remarks to the more important lesions which demand early recognition, and, as a rule, prompt surgical intervention.

The majority of acute abdominal cases may be referred to one or other of the following groups:

1. Acute intestinal obstruction.
2. Gastric and intestinal ulcers that have perforated.
3. Acute inflammatory lesions of septic origin.

Ruptured tubal gestation, twisted ovarian pedicle, and traumatic lesions of the abdominal viscera do not come within this classification, and will be referred to separately.

ACUTE INTESTINAL OBSTRUCTION.

Acute intestinal obstruction, as a primary affection, is most often due to strangulated hernia, external or internal; intussusception comes second in the order of frequency, while impacted gall stones and volvulus are less common causes. Not infrequently acute obstruction is grafted on to the chronic type. This is seen most often in cancerous stricture of the large intestine, the contracted lumen of the bowel being blocked by a mass of hard faeces.

Whatever the cause the symptoms are sudden in onset and progressive in character. The abdominal pain is diffuse and, while never quite in abeyance, is subject to periodic exacerbations caused by spasmodic contractions of the intestinal muscles in their endeavour to overcome the obstruction. The exhibition of opium may more or less completely mask the intestinal peristalsis, and it ceases entirely on the advent of peritonitis, but it is incorrect and misleading to assert, as is asserted by the authors of a well-known book on surgery, that "in acute cases intestinal paralysis dominates the picture."¹

Vomiting of a reflex character is frequently associated with the onset of the attack, but inasmuch as it is one of the initial symptoms of nearly all abdominal storms, it has no special significance.

The typical vomiting of acute obstruction sets in later, sometimes within a few hours, sometimes not until one or more days afterwards. Once it begins it continues with ever-increasing frequency, while the character of the vomited matter degenerates from bile-stained mucus to a brownish faecal-smelling fluid. Except in the rarely seen Richter's hernia, where only a portion of the circumference of the bowel is involved, there is complete obstruction to the passage of faeces and flatus. The abdomen gradually becomes distended, but until the onset of peritonitis it is neither tender nor rigid. The temperature and even the pulse may not show any marked departure from the normal for a day or two.

Strangulated External Hernia.

Strangulated external hernia requires little comment, but, as it is by far the most common cause of acute obstruction, it should always be thought of, and sought for, in the first instance.

Internal Strangulation.

Internal strangulation is most often caused by bands, the products of antecedent local peritonitis, a history of which may be obtained in many cases. They extend between the omentum, appendix, or Fallopian tubes and other parts of the abdomen. They give rise to hyperacute symptoms, with early vomiting. The patients are usually under 40 years of age. Strangulation by Meckel's diverticulum, and through chinks in the omentum, or broad ligaments, or in retroperitoneal pouches, are all rare, and cause symptoms similar to those produced by bands.

Post-operative Obstruction.

Post-operative intestinal obstruction requires a brief notice. It is nearly always due to kinking of the small intestine consequent on adhesions, and at first the mesenteric vessels are not implicated. It is seen most often after operations for acute appendicitis, the symptoms appearing about the end of the first week, and after the patient has apparently reached "smooth water." At first there are merely sharp attacks of colicky pain, and occasionally the intestinal peristalsis is sufficiently powerful to stretch the adhesions and effect relief; but, if not, the typical symptoms of obstruction gradually supervene. As the patients are under trained observers from the onset, operative measures for the relief of this form of obstruction are usually resorted to in good time.

Acute Intussusception.

Acute intussusception is the most common form of obstruction in children, and the clinical picture it presents is seldom obscure. The intermittent character of the pain is very pronounced, indeed the little sufferer may fall asleep between the attacks, which recur at intervals of a few minutes. A curved sausage-shaped tumour, which hardens at the onset of each paroxysm of pain, can almost always be detected somewhere along the course of the colon, while the right iliac fossa appears unduly empty. After a few hours there will be an escape of blood-stained mucus from the anus, and later still the intussuscepted bowel may sometimes be felt in the rectum. Obstructive vomiting is later in making its appearance. In young children there may be severe shock from the first.

Volvulus.

Volvulus occurs after middle life in patients who have suffered from chronic constipation. It concerns most often the sigmoid flexure, but occasionally the caecum is involved. Its most characteristic sign is the rapid onset of abdominal meteorism. The enormously-distended bowel can usually be outlined through the abdominal wall. Vomiting is a late symptom.

Obstruction from Gall Stones.

Obstruction from large gall stones that have ulcerated into the duodenum from the gall bladder is almost limited to elderly women. There will be a history of biliary trouble, and the impacted calculus may occasionally be felt through the abdominal wall. The symptoms are not usually very acute, and relief frequently comes by the stone passing onwards into the large bowel. I have, however, on two occasions seen hyperacute symptoms from this cause.

When acute obstruction supervenes in malignant stricture of the colon the symptoms appear gradually, and abdominal distension is always an early and pronounced factor. Owing to the muscular hypertrophy and accompanying dilatation of the colon on the proximal side of the stricture the peristaltic movements are remarkably powerful. There will be a history of increasing difficulty in getting the bowels to act, and long periods of absolute constipation may alternate with attacks of diarrhoea.

Contrary to what one might expect, the growth may for a long time produce little or no effect on the patient's general health. Indeed, in the last two cases I have seen there had been a distinct gain in weight during the preceding few months with, apart from constipation, no evidence of failing health or strength. The patient will frequently be able to locate the site of obstruction by noting where the peristaltic wave is arrested, and confirmation is afforded by ascertaining the amount of water that can be introduced per anum when the hips are raised on a pillow.

GASTRIC AND INTESTINAL ULCERS.

Perforating ulcers are found in the stomach, the duodenum, the lower end of the ileum, and in the large intestine. In the latter situation they are usually secondary to malignant disease. In the lower ileum they form one of the complications of typhoid fever, appearing during the third week or later.

Gastric ulcers are conveniently divided into the acute and the chronic varieties. The former are often multiple, and occur in young anaemic women. They are especially prone to perforate when situated on the anterior wall.

The chronic ulcer is usually single, of large size, and situated on one or other side of the pylorus. It occurs most often in men between the ages of 30 and 60 years.

The acute ulcer may run a latent course until it perforates, but in most cases there will be a definite history of pain on taking food. The pain is relieved by vomiting, and the vomited matter often contains dark blood.

There is usually a well-defined tender spot to the left of the middle line. When perforation is threatening the pain becomes continuous and the left rectus muscle rigid.

Duodenal ulcer gives rise to pain, which comes on one or more hours after meals, and is relieved by taking fresh food, the entrance of which into the stomach, by causing pyloric contraction, arrests for the time being the flow of the irritating gastric juice.

The symptoms of perforation are rarely ambiguous. The patient is suddenly seized with agonizing pain, which, in the case of gastric and duodenal ulcers, is situated in the upper abdomen. The pale, anxious countenance, the small, rapid pulse, and the subnormal temperature, attest to the presence of shock, which may, however, vary greatly both in respect of its intensity and duration. Locally, the most constant and characteristic sign is board-like rigidity of the recti muscles, with total cessation of abdominal respiratory movements. In a minority of cases the area of hepatic dullness is diminished or lost, owing to the escape of gases into the peritoneal space.

ACUTE INFLAMMATORY LESIONS OF SEPTIC ORIGIN.

Of the acute inflammatory lesions I shall refer only to cholecystitis, salpingitis, and appendicitis. (Septic peritonitis is always a sequel to some other disease. It will be dealt with in connexion with appendicitis.)

They have the following symptoms in common: Abdominal pain, more or less continuous; abdominal tenderness, at first diffuse, then becoming localized; rigidity of the overlying muscles; and, with the advent of suppuration, rigors.

The constitutional disturbances will show themselves in pyrexia, always greatest in the evening; increased pulse rate; a coated tongue with anorexia, thirst, constipation; and scanty high-coloured urine loaded with urates. Vomiting is usual, but it is not of a progressive character.

Cholecystitis is seldom seen apart from gall stones, a history of which will be forthcoming. The patients are nearly all elderly, and often fat, women. Palpation will in most cases reveal a distended gall bladder, which should not be mistaken for anything else.

Acute salpingitis is an ascending infection. A vaginal examination will define the swollen and exquisitely tender tubes, and the diagnosis will be strengthened by a history of antecedent or coexisting vaginal or uterine catarrh. In very acute cases the constitutional disturbances are apt to be alarming, and marked tympanites is nearly always present. In most cases, however, under expectant treatment, the storm becomes localized to the pelvis in a day or two.

Appendicitis.

Appendicitis has been so often discussed, that one is almost tempted to apologize for alluding to it. Its relatively great frequency, however, and the importance of duly appreciating its manifold phases, give it easily the first place among the lesions we are considering.

Of 427 abdominal emergency operations performed in the Sheffield Royal Infirmary during the last three years, 264 were for acute appendicitis, while during the same period the appendix was removed 110 times after the subsidence of one or more attacks.

We are still in the dark regarding the precise causation of the disease and of its alleged greater frequency during the last two decades; but when we consider its richness in lymphoid tissue, its low vascularity, and its dependant position, which militates against the easy escape of its contents into the caecum, we cannot feel surprised that it should be so vulnerable to attacks of inflammation. Its resemblance to the tonsils, both as to its structure and liability to septic infection, seems to justify the title "abdominal tonsil" which has been applied to it.

There are many grades in the severity of appendicular inflammation, and it will make for clearness if I begin with the mildest departure from the normal and ascend step by step to the most severe.

Following this plan, appendicular colic due to concretions or to mucus retained by kinking or constriction of

the lumen, claims brief attention. It causes fairly sharp, colicky pains in the region of the appendix, but has no other untoward symptoms.

The next grade in severity is a simple catarrhal inflammation of the mucous lining, with mild constitutional disturbances and slight local pain and tenderness. Under suitable expectant treatment the symptoms subside in two or three days.

Next we have suppurative catarrh with more or less ulceration, or even gangrene of patches of the mucous membrane. The appendix is swollen, and flakes of lymph may be found on its peritoneal surface, but as yet there is no perforation.

This grade gives rise to severe symptoms. The temperature may run up to 103° or 104° F. in the evening, and the pulse to 120 per minute. The localized pain, tenderness, and rigidity are all pronounced, and a definite lump can usually be detected.

The progress of these cases may be either towards resolution or to perforation. If in the first-named direction, amelioration of the symptoms will set in on the second or third day. Perforation is revealed by a sharp increase in the pain, perhaps after it had begun to subside, by an increase in the pulse-rate, and by rigors.

If the appendix has been walled off by lymph before perforation actually takes place, the temperature will rise in ratio with the pulse, which will be full and bounding, and the iliac lump will become larger and more tender. After the storm caused by perforation has abated, the patient may look and feel better, and the symptoms of an acute abdomen may give place to those of a localized abscess.

In the less fortunate cases, where perforation is not preceded by lymph formation, or where the amount is inadequate to exclude the diseased appendix from the general peritoneum, we have grafted on the train of symptoms seen in the worst grade of the disease, the fulminating variety, in which the entire appendix is the seat of acute gangrene.

These symptoms, which are those of acute diffuse peritonitis, should be graven on our memories, because early diagnosis of the condition, followed by immediate operation, is necessary to the rescue of the unfortunate patient from what would otherwise be a certain and speedy death.

The patient may have been ill for a few days from what appeared to be an ordinary attack of appendicitis, or, more commonly, he is seized without previous warning. There will be intense pain in the right iliac region, rapidly extending to the rest of the abdomen. The face will be pale and anxious; the pulse rapid, small, and hard; and the temperature erratic—in the worst cases subnormal. The abdomen ceases to participate in the respiratory movements, becomes rigid and tender all over, and later distended and tympanic. The legs are drawn up to relax the abdominal muscles and protect the body from the weight of the bedclothes. There is intense thirst with incessant vomiting, the vomited matter welling up apparently without effort on the part of the patient. The distended intestines become paralysed and their contents motionless. The heart beats ever faster and weaker, and the failing circulation manifests itself in the blue and cold lips and extremities. Towards the end mild delirium supervenes, and with its advent the patient ceases to complain of pain or even of tenderness.

Ruptured Tubal Gestation.

Ruptured tubal gestation should be suspected when during the second or third month of a supposed pregnancy the patient is seized with acute pain in the lower abdomen. There may have been nothing aberrant in the previous history of the case, but colicky pelvic pains and irregular uterine haemorrhages are not uncommon. The rapid outpouring of blood from the torn vessels is indicated by blanched lips, a fast soft pulse, great restlessness, and an incessant cry for more air. A bimanual examination will reveal a lump in one or other broad ligament, and possibly fluctuation in the pelvis behind the uterus.

Twisted Ovarian Pedicle.

Twisted ovarian pedicle is indicated by a sudden increase in the size of the tumour conjoined with the signs of subacute peritonitis in the lower half of the abdomen. Ascitic

fluid is rapidly poured out, and in the absence of a definite history may mask the true condition.

INJURIES.

Injuries to the abdominal viscera may result in acute infective peritonitis from the escape of the contents of the stomach, intestines, or bladder, or in severe loss of blood from rupture of the liver, spleen or kidneys. When the mesentery is torn, in addition to internal hæmorrhage there is the danger of the corresponding section of the bowel becoming gangrenous.

Severe shock is apt to be produced by abdominal contusions, even in the absence of gross visceral lesions, and we must in many instances be satisfied at first to wait and watch the progress of the case. The nature of the agent concerned in the injury, and the locality of its impact, may afford assistance in diagnosis, as may also an examination of the urine. Should the shock persist or deepen after an hour or more of watching, or should there be clear evidence of progressive internal hæmorrhage, or of commencing peritonitis, the abdomen must be opened forthwith, and the condition dealt with according to its necessities.

DIFFERENTIAL DIAGNOSIS.

The chief difficulties in abdominal diagnoses are a fat abdomen, inability to elicit an exact history of the symptoms, and the order in which they appeared, the advent of peritonitis which overshadows the primary mischief, and the highly reprehensible habit which is still occasionally seen of giving opiates before the nature of the abdominal lesion has been revealed. By masking the symptoms, particularly the pain, it deludes the patient, and sometimes the doctor, into the belief that all is going well when such is not the case, and may be instrumental in delaying urgently necessary operative help. Moreover, opium inhibits peristalsis and diminishes leucocytosis, thereby seriously handicapping the patient's progress.

While in some cases it may be impossible to predict the nature of the catastrophe previous to exploration, one cannot too strongly deprecate the indiscriminate resort to abdominal section as a short cut to diagnosis.

A careful investigation of the history of the case, and of the order of onset of the symptoms, conjoined with the physical signs present, will seldom fail to indicate the nature of the lesion we are called on to deal with, and will permit of orderly preparation being made for whatever surgical measures may be necessary. The advantage of a thought-out plan over a haphazard operation is too obvious to need emphasizing.

When called on to investigate an acute abdominal case, we should keep in mind the threefold classification I have outlined.

In acute obstruction the remittent character of the pain, each exacerbation of which is accompanied by intestinal movements; the complete block to the passage of faeces and flatus; the progressive vomiting; the increasing abdominal distension; and the absence of pyrexia and of abdominal muscular rigidity, make up a picture easily read.

The sudden onset of agonizing pain in the upper abdomen of a young anaemic female, especially if there have been previous symptoms of stomach troubles, is highly suggestive of ruptured gastric ulcer, and, if accompanied by shock, abdominal tenderness, board-like rigidity of the recti muscles, and absence of abdominal respiratory movements, the suggestion becomes almost a certainty.

An antecedent history of pain coming on one or more hours after meals and relieved by taking fresh food will direct attention to the first part of the duodenum as the probable site of perforation.

The diagnosis of acute appendicitis is rarely difficult. Along with the general symptoms of inflammatory fever there will be in the right iliac region localized pain, localized tenderness, and localized muscular rigidity. In a large proportion of the severe cases there will also be a localized swelling, but it must not be forgotten that in the very worst cases this sign may be absent. An inflamed appendix, if directed upwards behind the caecum, may simulate renal trouble, and, when it lies wholly or in part in the pelvis, it may give rise to bladder or rectal irritation. In obscure cases leucocytosis, particularly if it increases from day to day, is suggestive of appendicular abscess.

TREATMENT.

Strangulated hernia, if seen early, should be reduced by gentle taxis, but, if there is the least doubt respecting the integrity of the bowel, taxis should give place to operation. If the patient's condition is good, and the bowel is not seriously damaged, a radical cure should be effected forthwith. It is not only a safeguard against recurrence, but is also a barrier against peritoneal infection from without. When the bowel is found to be gangrenous, wide resection with end-to-end anastomosis may be attempted in young and vigorous patients who do not show signs of profound toxæmia, but the majority of gangrenous cases are too ill to justify this procedure.

It is well to remember that unoperated-on cases have recovered, with, of course, an artificial anus, and that in very bad cases of gangrene the best treatment may be to make a simple incision into the sac without disturbing the exuded lymph, which has probably sealed off the peritoneum.

Obstruction from bands and other similar causes should be sought for systematically. The condition of the caecum is first ascertained. If it is empty, the obstruction will be found by following the small intestine upwards. The possibility of more than one point of obstruction being present must be borne in mind.

After freeing the obstruction, the condition of the bowel must be carefully investigated. If the portion above the constriction is much distended, and does not speedily discharge itself into the lower part, it should be withdrawn outside the abdomen, securely packed off with gauze, and opened on its antimesenteric border. After its contents have escaped, the opening is closed with a continuous suture. Advantage may be taken of the opening to introduce a saline aperient into the bowel. The establishment of an artificial anus in the small intestine is fraught with so many disadvantages and dangers that it should, if possible, be avoided.

Intussusception should, as a rule, be dealt with by operation. If seen early, an opening long enough to admit two fingers is sufficient. The procedure of reduction is of the simplest character, and need occupy only a few minutes. If for any reason operative measures are ruled out of court hydrostatic pressure may be tried. In quite early cases it will often be effectual; but the drawback to its use is that we cannot always tell whether the reduction is complete or not, and so valuable time may be lost. Should reduction be impossible resection of the involved segment of bowel must be performed, but it is nearly always unavailing in young children. A Paul's tube should be tied into each end of the cut bowel and the restoration of the intestinal canal left until a subsequent date.

To prevent recurrence after reduction the bowel should be anchored by a suture and an opiate given.

Gall stones become impacted in the small intestine, usually near its termination. After causing obstruction for a day or more they may be forced on into the caecum. They do not produce strangulation of the mesenteric vessels, and unless the symptoms are very acute, medical measures, such as the administration of belladonna, with hot fomentations to the abdomen, should be tried before having recourse to surgery. The treatment of volvulus is far from being satisfactory. It is usually quite impossible to reduce the twisted bowel, even after its contents have been allowed to escape. The best immediate treatment is to create an artificial anus. Later, the involved segment will require either excision or exclusion by short circuiting.

Acute obstruction secondary to a cancerous growth in the colon should be relieved by a proximal colostomy, the cancer being dealt with after the acute symptoms have passed away. Resection with immediate anastomosis of the colon in the presence of acute obstruction, is hardly ever successful and should not be attempted.

Where the patient is obviously too ill to stand much operative interference a short abdominal incision may be made under local anaesthesia, and a Paul's tube tied into the first coil of distended bowel encountered. Lives have occasionally been prolonged by this simple expedient; but it is unavailing in the presence of gangrene of the bowel.

In advanced cases of acute obstruction the stomach should be washed out preliminary to operation, in order to avoid the grave danger of vomited matter being drawn into the lungs during anaesthesia.

Ruptured gastric and duodenal ulcers should be closed by a double row of continuous sutures inserted well away from the friable edges of the perforation. Additional security is afforded by covering the line of suture with a piece of omentum. Should it be impossible to close the opening it must be drawn up to the surface, and, after anchoring the stomach walls to the parietal peritoneum, surrounded with gauze packing. Where the rupture has occurred soon after a meal, or a long interval has elapsed before operation, there will be extensive peritoneal fouling, and the abdomen will require thorough and systematic flushing. Towards the finish the shoulders should be raised to allow the saline solution to gravitate towards the pelvis.

If the rupture is a recent one, and particularly if the stomach was empty at the time, the soiling may be strictly local, when it is best dealt with by dry mopping. In all cases a pelvic drain tube should be introduced through a median suprapubic puncture, and the patient placed on a sloping bed.

Should gastro-enterostomy be indicated it is better to postpone its performance till a later date.

The treatment of appendicitis is a subject around which much controversy has taken place, and is still far from being settled.

In common with the majority of surgeons I believe that if all cases of acute appendicitis were operated on within the first few hours from the onset of symptoms we should have fewer deaths from the disease and a reduction in the average period of incapacity from work caused by it. At this very early stage the operation is easily performed and has hardly any risk as to life. During the three years 1905-8 there was not a single fatality among 57 patients operated on in the Sheffield Royal Infirmary for acute appendicitis uncomplicated with extra-appendicular abscess. In many of these cases the appendicular canal was full of pus and the mucous membrane gangrenous.

The objection, however, on the part of a large section of the public to operations that may not be absolutely necessary to life, and the hope in each particular case that, after all, non-operative measures may suffice, have hitherto, and will I fear always constitute difficulties in the way of very early interference.

If the case has not been seen, or if the question of operative interference has not arisen until after the lapse of twenty-four hours, it is probably better to postpone operation unless the symptoms are both acute and progressive. Mild cases usually begin to subside on the second day, and if carefully watched may be safely left until the storm has passed.

Immediate operation is called for during any stage of the disease by (1) a rapidly increasing pulse rate, particularly if unaccompanied by a corresponding rise in the temperature; (2) the recrudescence of acute pain in the appendicular region after it had subsided, or a sudden increase in the severity of the pain; (3) extension of the pain, tenderness, and muscular rigidity to other parts of the abdomen; (4) commencing abdominal distension with or without vomiting; (5) rigors; (6) an increase in the size of the appendicular swelling after the third day; and (7) a change for the worse in the patient's expression.

If there is irritability of the rectum with, perhaps, an abundant escape of mucus, we should suspect and examine for a pelvic abscess.

Operative Details.

As to operative details, I shall only allude to abscess cases and to those grave and, until quite recently, commonly fatal, cases in which septic infection has spread from the appendix to the general peritoneum. The former may be dealt with by direct incision into the abscess cavity in cases in which the abscess is large and well encysted; or, if there is any doubt on the latter point, by opening the peritoneum to the inner side of the swelling, and, after waling off the intestines and pelvis with gauze, raising up the caecum from the outer side, when the abscess will be exposed. The diseased appendix should be removed when it can be easily reached, but we are not justified in running the risk of peritoneal infection by vigorous or prolonged efforts to remove it if deeply placed. In upwards of 90 per cent. of abscess cases treated by drainage alone there is no further appendicular trouble, while in the small minority of

cases where a fistulous track will not close the offending appendix can be safely removed on a subsequent occasion.

Owing largely to the work of American surgeons, the treatment of acute diffuse peritonitis, whether secondary to perforative appendicitis or other abdominal lesions, has been entirely revolutionized; and, although Murphy's experience of 35 recoveries out of 36 consecutive cases of acute general peritonitis will probably long remain a record, there can be no doubt that a great reduction has been effected in the mortality-rate of this dread disease. The improved method of treatment is in some respects a reversion to the elementary principles of surgery long known and practised in dealing with acute inflammations elsewhere in the body. In other respects it utilizes recent additions to our knowledge of the physiology and pathology of the peritoneum.

It recognizes that the patient's first and most important line of defence against the ravages of peritoneal infection lies in the undamaged endothelial cells which clothe the abdominal walls and viscera, and that it is worse than useless to try to remove, or to destroy by chemical means, the invading bacteria, because not only is it impossible to do so, but the attempt involves grievous damage to the peritoneal surface and opens up fresh channels through which the septic toxins can gain access to the circulation. It substitutes for the heroic scrubbing, flushing, and evisceration of former times the simple treatment applicable to an acute abscess that has formed around an infected substance elsewhere in the body. It consists in—

1. Removal of the primary cause of infection with the least possible interference with the surrounding tissues. No attempt is made to wash away pus or to remove exuded lymph. (In very bad cases, as I shall show presently, removal of the appendix may be omitted.)

2. The provision of free abdominal drainage so as to relieve tension with all its accompanying evils. A Keith's tube inserted into the pelvis is usually sufficient, but it may be supplemented by others of india-rubber leading down to the site of the appendix and elsewhere.

3. Placing the patient on a sloping couch so that the shoulders shall be on a considerably higher level than the pelvis. Sufficient elevation is secured by placing the head castors of the bed on two kitchen chairs. The primary object of this posture is to permit of the descent of septic material towards the pelvic basin, where the rate of absorption by the lymphatic vessels is much slower than in the upper abdomen. It likewise enables the patient to breathe better and to more easily get rid of accumulations of gases in the stomach.

4. Giving large quantities of saline solution by the bowel. The large intestine, particularly the caecum, readily absorbs water, which is badly needed by the poisoned tissues, but which cannot be retained by the stomach. By introducing a large amount of water into the system it is contended that peritoneal absorption is not only arrested, but that, by a reversal of the stream, the poisons already taken up are eliminated.

The saline solution may be given continuously by means of a rectal tube with several terminal openings connected with a reservoir, which should be placed a few inches higher than the level of the rectum. The flow should be so adjusted that from one to two drops escape each second. Where the continuous method is inapplicable, or is irksome to the patient, it may be replaced by the intermittent plan, half a pint being very slowly introduced every two hours or so through a funnel and tube. In very bad cases anti-streptococcal serum may be given.

Secondary abscesses should be promptly evacuated and drained, and threatening intestinal obstruction met by immediate intervention.

Nothing should be given by the mouth for twenty-four hours or longer, and vomiting should be dealt with by washing out the stomach. Distension is relieved by turpentine enemata. Purgatives are unnecessary, the bowels acting naturally on the second or third day.

Murphy stipulated that in all cases of general peritonitis the source of infection, whether it be a ruptured gastric ulcer or a gangrenous appendix, must be dealt with.

In hospital practice one meets with not a few cases of neglected appendicitis, with wide peritoneal infection, where the patient is so very ill that even the minimum interference advocated by Murphy would almost certainly

hasten rather than retard the impending dissolution; and yet some of these cases may be rescued by the very simple procedure of making a suprapubic puncture, under local anaesthesia, and passing a Keith's tube down into the pelvic basin. Recovery is, of course, slow on account of the prolonged suppuration which necessarily accompanies Nature's method of shedding the gangrenous appendix; but I am firmly persuaded that several of my patients owe their lives to the restriction of operative measures to the extent I have indicated, combined with the other adjuncts to treatment that I have already mentioned.

The procedure can be carried out at once, without moving the patient to hospital or wasting valuable time in elaborate preparations.

The prospect of success in ruptured gastric and duodenal ulcers is less hopeful, but even in these cases it should be tried if more ambitious measures are out of court. Upwards of a year ago I saw with Dr. Buckley, of Chesterfield, a man who had a ruptured duodenal ulcer of forty-six hours' duration. There were all the evidences of diffuse peritonitis; the pulse was barely discernible, and the extremities were blue and cold.

Our surgical armament was, I think, a record in simplicity. It consisted of a razor in lieu of a scalpel, a piece of gas rubber tubing, a few forceps, and a sauceman. The patient, although he ultimately died, made a splendid rally, and seemed to justify for a time the hope that he might recover.

APPENDICOSTOMY IN DIFFUSE SEPTIC PERITONITIS.*

By WILLIAM BILLINGTON, M.B., M.S. LOND., F.R.C.S.,
SURGEON TO OUT-PATIENTS, QUEEN'S HOSPITAL, BIRMINGHAM.

In the *Annals of Surgery* (February, 1906) Murphy of Chicago published an account of his now well-known method of treatment of diffuse septic peritonitis. In brief, this consists in rapid elimination of the cause of the peritonitis—for example, the removal of a gangrenous appendix; free drainage of the peritoneum by means of rubber tubes passed through the operation wound and into the bottom of Douglas's pouch through a suprapubic puncture; the assumption by the patient of the semi-sitting position after operation; the prevention of peristalsis by withholding all food and fluids by the mouth; and the introduction into the circulation of large quantities of fluid by absorption from the rectum. He claims that in this way the current in the lymphatics of the peritoneum is reversed, that membrane becoming a secreting instead of an absorbing surface, with the result that septic matter is washed away in the free flow that takes place through the drainage tubes. Further, toxins already in the blood are diluted and their elimination facilitated by the free diuresis that is induced. Murphy states that only one death occurred amongst the last 29 cases treated by him in this way.

Of the value of this method of treatment there can be no doubt. Success, however, largely depends upon the quantity of fluid that the rectum can be made to absorb. Murphy introduces a nozzle with three or four openings into the rectum, and attaches it by means of rubber tubing to a bag containing warm water. The bag is slung 3 or 4 in. above the plane of the rectum, so that the water runs in at very low pressure, and all distension of the bowel is avoided. I have attempted to carry out this treatment on many occasions, but have never succeeded in getting the rectum to absorb the large quantities of fluid that Murphy mentions. With the patient sitting in a nearly upright position it is almost impossible to prevent leakage through the anus. This not only nullifies the procedure but causes the patient a good deal of annoyance. In many cases also the rectum becomes very intolerant of the prolonged presence of the tube, and straining occurs. Many other surgeons whom I have specifically questioned upon this point appear to have experienced the same difficulty.

* This paper was written before Mr. Keetley read his paper on the utility of the appendix before the Surgical Section of the Royal Society of Medicine. I believe no better example of the value of appendicostomy can be given than in the treatment of desperate cases of diffuse septic peritonitis.

It occurred to me that the appendix might with advantage be utilized for the purpose of introducing fluid into the large bowel, and on several occasions I have done so with marked success. When the appendix is healthy—for example, in peritonitis following perforation of a gastric ulcer—an incision is first made over the lesion, which is rapidly treated in such a way as to prevent further contamination. No attempt is made to cleanse the peritoneum by irrigation or mopping, but adequate drainage is provided for, preferably by means of rubber tubes passed through the wound. Then, instead of making a suprapubic puncture to allow of the introduction of a rubber tube into Douglas's pouch, the abdominal cavity is again opened by a small vertical incision over the lower part of the right rectus, the fibres of which are separated. The appendix is pulled up into the wound, and the distal portion cut off. The stump is then fixed in the upper angle of the wound by one or two silk sutures passing through all its coats and the skin. The open mouth of the stump is thus practically flush with the skin, and through it a small rubber catheter is passed into the caecum. A large rubber drainage tube is finally passed to the bottom of Douglas's pouch through the lower part of the wound. The patient is then put back to bed, with the rubber catheter projecting through the dressings, care being taken to prevent it being accidentally pulled out. Finally, the patient is placed in the Fowler position, and the catheter connected by rubber tubing to a tank in which is warm normal salt solution. The tank stands on a table at the bedside, and should not be more than 3 in. above the plane of the caecum. The flow of water is regulated by a clamp on the rubber tubing.

If the peritonitis is secondary to disease of the appendix, the above procedure must be modified somewhat. An incision is then made over the appendix and its condition ascertained. If, as is often the case, the part nearest the caecum is comparatively healthy, the distal portion is cut off and the stump sutured to the skin, as already described. If this is impracticable, the appendix is extirpated in the usual way and a small portion of the caecal wall nearest the surface sutured to the skin. A puncture sufficient to admit the rubber catheter is then made in it. It is advisable in these cases to introduce a large rubber tube into the pelvis through a separate suprapubic puncture.

I use normal salt solution in preference to plain water, believing it to be less irritating to the mucous membrane of the bowel. Not more than 1 pint per hour is admitted in order to avoid distension, and care must be taken not to place the supply tank at too high a level. When absorption ceases, as much fluid is evacuated from the rectum as is introduced into the caecum, and the supply is then cut off. It is not necessary to leave in the catheter for more than forty-eight hours. At the end of that time it is withdrawn, the mucous membrane of the stump of the appendix is removed for a little distance down, and the opening closed by uniting the sero-muscular coats with a catgut stitch. Finally, any adhesions between the skin and the stump are gently broken down and the latter allowed to retract. In this way the risk of a faecal fistula is minimized.

In practice this procedure has many advantages over that employed by Murphy. It does not prolong the initial operation by more than two or three minutes. I have removed a gangrenous appendix, sutured the stump in the wound, and provided for drainage, with the patient on the operating table for only twelve minutes. The quantity of fluid admitted to the bowel can be regulated exactly, while the whole length of the large intestine takes part in its absorption. The patient suffers practically no discomfort, as no disturbance of bedclothes is necessary, and there is no leakage from the anus until absorption is at an end. Further, stimulants and nutrients can be easily and rapidly administered, if desired, by simply disconnecting the tank and connecting the catheter to a glass funnel into which they are poured.

Illustrative Case.

Mrs. A., aged 35, was admitted into the Queen's Hospital on August 4th, 1903. Three weeks prior to admission she had aborted, and two weeks later was seized with severe hypogastric pain, which had become much worse lately. When seen she presented the typical appearance of advancing peritonitis. The temperature was 103°, and the pulse 140, small, and thready.

The whole abdomen was rigid and tender, and the lower half tumid.

The abdomen was opened in the middle line, when a considerable quantity of brownish-yellow free pus escaped. The pus was not faeculent. On examining the pelvis an opening leading into an abscess cavity in the neighbourhood of the left Fallopian tube was found. Evidently the abscess had ruptured into the peritoneal cavity, and excited a generalizing peritonitis. The appendix, which was healthy, was cut across about 1½ in. from the caecum, and the stump fixed in the upper angle of the wound. A No. 6 rubber catheter was passed through the stump into the caecum. Two large rubber tubes were placed in Douglas's pouch, and brought out through the lower part of the incision, and the patient put back to bed. No attempt was made to cleanse the peritoneum.

The patient was propped up in the Fowler position, and a pint of warm saline solution passed into the colon every hour. Twelve hours later the pulse had fallen to 90, and was of good volume; the temperature was normal; the cheeks had filled out, and the patient looked and expressed herself as feeling very comfortable. The irrigation was kept up for twenty-four hours, during which time 34 pints of saline solution passed into the bowel. Of this only about 5 pints escaped from the rectum. There was a copious discharge from the tubes, and a large amount of urine excreted. The catheter was withdrawn from the appendix, and on the second day the silk stitches connecting it to the skin were cut, and the stump allowed to retract. No escape of faecal matter occurred, then or later. Subsequent progress was uneventful, and the patient was discharged at the end of three weeks, with a single tube from which there was very little discharge.

APPENDICOSTOMY: WITH NOTES ON THE SURGICAL ASPECT OF COLITIS.*

By J. BERNARD DAWSON, M.B., B.S., F.R.C.S.,

LATE HOUSE-SURGEON ST. MARK'S HOSPITAL.

The appendix vermiformis, which has occasioned a literature probably unequalled by that of any other part of the human system, seems of late to have, in some measure, justified its existence. Instead of being regarded as an unnecessary and dangerous possession, there have been found for it uses. The operation of appendicostomy, whereby the appendix is used to establish a temporary or permanent communication with the exterior, was first proposed in 1894¹ by Keetley, who suggested that by bringing the appendix through the abdominal wall and amputating the apex it might be used as a spout to relieve the distension of a case of obstruction occurring at a point below the caecum. He put this suggestion to the test during 1906. The credit of first performing the operation seems to be due to Weir, of New York, who in 1902² reported a case of ulcerative colitis upon which he performed the operation with marked success.

THE OPERATION.

The surgical procedure is simplicity itself. Nevertheless, although, as in Weir's original case, the appendix may conveniently present itself, yet if adhesions be present, if the organ is kinked, or if it passes behind the caecum, the operation may be long and difficult, rarely, however, should it be found impossible to liberate a sufficient length of well-nourished appendix to extend through the thickness of the abdominal wall. A small oblique incision, large enough to admit two fingers, is made through the abdominal wall in the region of McBurney's point. If the split flap method is used, the muscular fibres should be notched at right angles to their direction. Otherwise the vessels in the meso-appendix may be so constricted as to cause sloughing of the organ. If the appendix is free it can at once be brought out through the wound; if, however, there are adhesions, or the appendix is for some reason inaccessible, the incision must be enlarged. The appendix should be pulled out until the caecum is flush with the parietal peritoneum, care being taken that there is no twist in its mesentery. Two fine silk sutures are inserted to secure the meso-appendix and the free border of the appendix to the edges of the incision in the peritoneum. The muscles are allowed to fall back, and if necessary brought into apposition with a loosely tied catgut suture. The skin incision is sutured, the last suture taking in the sero-muscular coats of the appendix protruding through one angle of the wound. A dressing of gauze and collodion is applied, covered by wool and bandage, and the patient returned to bed.

Two or three days later the tip of the appendix is severed within ½ in. of the skin and the appendical artery secured. The exposed mucous membrane is caught with fine catch forceps, dragged out a little and secured by one or two sutures to the edge of the skin. A rubber catheter is introduced into the caecum, and, if desirable, irrigation or other treatment can be at once proceeded with. If difficulty is experienced in passing the catheter, one designed by Mr. Keetley, having a tapering solid end extending beyond the eye of the instrument, can be used. Beyond a slight risk of infecting the wound, there is no reason why the appendix should not be opened and a catheter introduced at the time of the operation, if immediate entry is required. Should the lumen be small, it is very easy to dilate it gradually to admit a No. 10 or 12 English. It is desirable to leave the catheter in continuously during the first ten days to overcome any tendency to contraction on the part of the wound producing stenosis of the appendical lumen. Later it is sufficient to pass the catheter once daily.

There are several difficulties which may arise in the operation:

1. In the first appendicostomy I saw performed the surgeon, accustomed to appendicectomy, inadvertently tied part of the meso-appendix. Subsequently the distal end of the appendix sloughed below the level of the skin, but, fortunately, not below the level of the muscular layers. The only consequence was a great tendency of the opening to close.
2. A similar condition occurred in another case, in which the appendix was kinked upon itself in such a manner that only sufficient was obtained to just reach the skin margin.
3. When the tip is amputated, unless the mucous membrane is secured to the skin edge at once, it retracts within the sero-muscular coats, and a tendency to stenosis arises.

THE POSSIBILITY OF THE OPERATION.

The question naturally arises whether there may not be a percentage of cases in which the appendix is so situated as to render appendicostomy impossible; in 100 autopsies at St. George's Hospital the appendix was a fibrous cord without a lumen in 2; in 2 the lumen admitted a bristle only; in 96 appendicostomy would have been possible.

INDICATIONS FOR APPENDICOSTOMY.

The following classification is modified from that of Jacobson and Rowlands.³

Appendicostomy may be performed:

1. For irrigation and medication of the colon.
2. For obstinate and protracted constipation.
3. For drainage of the caecum and relief of abdominal distension.
4. For nutritive purposes.
5. For irrigation and medication of the lower ileum.

THE SURGICAL TREATMENT OF COLITIS.

The terms, colitis or enteritis membranacea, pseudo-membranacea, pellicularis, tubularis, muco-membranacea, crouposa, fibrinosa, pseudo-enteritis, catarrhus desquamativus, diarrhoea membranacea, tubularis, etc., have been invented, but by my mind the condition is one simply of a mucous secreting epithelium covered membrane subject to inflammatory reaction of various degrees. There are, however, rare forms of colitis dependent upon definite and well recognized general constitutional disorders which do not come within the scope of this paper. Such are the colitis due to injury, pyaemia, diabetes, Bright's disease, purpura, scurvy, amyloid degeneration, venous or arterial stasis, and spinal cord lesions.

In dealing with colitis due to local lesions the question of some form of classification arises. The following is simple, and I think sufficient:

- Simple acute.
- Simple chronic.
- Ulcerative acute.
- Ulcerative chronic.

Whilst there are distinct cases both of simple and ulcerative colitis, yet the demarcation between these two varieties is by no means well defined. A simple inflammatory condition of the colonic mucosa may or may not proceed with greater or less rapidly to definite destruction of the mucous epithelium. Cases brought under notice in

* Read before the York Medical Society.

this intermediate stage have received names, some describing the macroscopic appearance, such as "follicular colitis," "granular colitis," "colitis punctata," and some suggesting an underlying nervous origin, such as "colica mucosa" and "nervous colitis."

I have avoided the use of the word "membranous," since the shreds and casts which, in some cases, are passed, have been conclusively shown to be inspissated mucus, containing a few epithelial cells and no leucocytes.

Acute simple colitis is a condition similar pathologically to acute pharyngitis. It may react to treatment or pass on to acute ulcerative colitis, or subside into chronic simple colitis.

Chronic simple colitis may be a sequela of acute simple colitis, or may arise without any apparent acute stage. It is similar pathologically to hypertrophic rhinitis, and has been called "colitis hypertrophica." It is justifiable to use the term "chronic simple colitis" when on examination with the sigmoidoscope the mucous membrane of the sigmoid is seen to be thickened, oedematous, and discharging copious mucus without ulceration. There may, of course, be some ulcers higher up which will account for the condition; but since it has been shown that in colitis the most marked destruction and damage occurs at the sigmoid, the absence of evidence there is sufficient for clinical purposes.

Acute ulcerative colitis is theoretically a sequela of acute simple colitis, but the inflammation may be so intense as to produce ulceration practically from the onset. Dysentery, due either to Shiga's bacillus or to the amoeba, is the commonest form of acute ulcerative colitis, but the condition may occur without either of the above organisms being present.

Chronic Ulcerative Colitis.—The ulceration may be superficial and punctate, consisting of erosions, or it may be extensive, serpiniginous, and progressive, passing on to pericolicitis, abscess, or to perforation. This form of colitis resembles the various forms of gastritis and gastric ulcer.

Mucous Colitis with Casts.—The so-called mucous-membranous colitis of nervous origin has been attributed to various causes by different authorities.

(a) Einhorn ascribes it to enteroptosis, and considers it a common associate of achylia gastrica.⁴

(b) Glenard considers it due to enteroptosis, which, by dragging on the bile passages, produces an alteration in bile tension and flow, causing a diminished secretion of mucus, which favours precipitation of mucus by acids in the intestine.⁵

(c) Geoffroy regards enterospasm as the chief underlying cause.⁶

(d) Letcheff and Akerlund give disease of pelvic organs a prominent place in the etiology.⁷

(e) Vanni, Mannaberg, and others adhere to the view that coprostasis is the predecessor of the condition.⁸

(f) Von Noorden regards constipation as the exciting cause, but only in neuroathenic and hysterical subjects.⁹

(g) Nothnagel prefers to consider the phenomena as due to hypersecretion of mucus from anatomically sound mucosa.¹⁰ Nothnagel quotes a case of a boy of 16 who in the course of acute endocarditis had a spinal embolism; in addition to the paraplegia, retention of urine, etc., which resulted, for several days he passed $\frac{1}{2}$ litre of clear thin mucus through his paralysed sphincter ani. No one who has appreciated the full distress of waiting to be called to a dreaded viva voce examination will deny the existence of nervous control over the movements and secretion of the colonic mucous membrane; but it is another thing to ascribe colitis of this type to a nervous origin. Since this is not a fatal disease *post-mortem* information is scanty, but that which Nothnagel himself presents is not at all conclusive.

Jagic and Weigert¹¹ describe a case of a woman, aged 43, who had had symptoms of colitis with passage of casts, and who died from diabetic coma. *Post mortem* the pancreas was atrophic; the kidneys, one atrophic and the other hypertrophic; the stomach and small intestine were normal; the large intestine contained faecal masses, and the mucous membrane was striated with adherent white viscous material, which on staining was shown to be mucus. There were no macroscopic signs of inflammation. Lieberkühn's crypts were distended, and the goblet cells swollen and broken off; but on microscopical examination the tissue round the crypts was found infiltrated with round cells in greater quantity than normal. Especially was this the case where the secretion of mucus was most abundant.

Pye-Smith¹² quotes the case of a woman of 50, who passed mucous casts for two years. Casts were found *in situ* after death, and could be washed off, showing a normal mucosa underneath. There was, however, a carcinomatous stricture in the sigmoid.

Rothmann's¹³ case had passed mucous casts for some time, and had been treated with rectal irrigation without improvement. The woman died of carcinoma of the base of the skull. *Post mortem*, the large intestine was found to contain some

faecal masses and thickened viscous mucus adherent to an obviously reddened and inflamed mucous membrane. An interesting point in this case was that the mucosa of the ileum was also inflamed, but without adherent mucus, thus tending to show that the inflammation was the primary condition.

Edwards¹⁴ describes a case of a man aged 71 who passed casts in his stools. He died of meningitis. No macroscopic change could be found in the mucosa, but a microscopic examination was not made.

Thus we find that of four cases of colitis with casts, in which a *post-mortem* examination was made, two showed inflammatory phenomena in the mucous membrane, in one there was a carcinomatous growth in the sigmoid, and one showed no change in the mucous membrane when examined macroscopically.

In a recent paper Lockhart Mummery¹⁵ gives particulars of 9 cases of colitis with passage of casts which he had under his care. The analysis of these cases provides the following figures:

Total number of cases 9 —

Female 7. Average age 41.7 years.

Male 2. Average age 46 years.

Careful sigmoidoscopic examination revealed the following conditions:

No case found	1 case
Chronic inflammatory condition of mucosa resembling that of granular pharyngitis	3 cases
Similar condition, but in addition shallow ulcers scattered over mucous membrane of rectum and sigmoid	1 case
Adhesions binding down sigmoid flexure	1 case
Cancer of sigmoid flexure	2 cases
Retroflected uterus pressing on rectum	1 case

It is such evidence as this that makes the position taken up by Nothnagel untenable. Apart from those cases showing a definite organic change, such as adhesions or new growth, the sequence of events seems to have been as follows:

1. Obstinate and protracted constipation almost always.
2. Possibly ingestion of drastic and irritating purgatives.
3. A catarrhal inflammatory condition of the mucosa.
4. Chronic ulceration of the colon of varying extent and depth, in some cases.

The influence of enteroptosis may be a primary one, producing or helping to produce the constipation, or the displacement of the viscera may be in part due to the retention of faecal matter. The average age of women, 41.7, is one at which a relaxed abdominal wall is common, for want of tone in the abdominal muscles is given an important place in the etiology of enteroptosis by Keith in his *Hunterian Oration*¹⁶ upon this disease.

The theory of nervous influences as a cause of mucous colitis seems to depend to no small extent upon the fact that it is a disease commonly associated with other neuroathenic symptoms. When the profound nervous phenomena which may accompany haemorrhoids are remembered, it is not surprising to find a similar condition in patients, usually women, suffering from obstinate constipation followed by diarrhoea and the passage of much mucus, possibly with severe pain.

TREATMENT.

A.—Of *Acute Simple Colitis*.

There are two points to which I should like to draw attention.

1. *The Diet.*—It is usual to put patients upon what is either strictly or approximately a pure milk diet. Whether this is satisfactory is very doubtful. The object of dieting in colitis is to produce faeces which shall be the least irritating to the inflamed mucosa. A milk diet, whilst leaving a small residue, produces faecal masses which are small, globular, very fine, and undoubtedly irritating to the colon, which has to undergo prolonged and strong contractions to pass along such small masses. Since they do not produce an efficient distension of the bowel they are apt to remain too long in contact with the mucous membrane. As a remedy for this von Noorden recommends a liberal diet of food which leaves a bulky residue of cellulose, articles such as brown bread and vegetables being freely given, together with a daily allowance of cream or other highly fatty material, producing motions which, being bulky, soft, well lubricated, and unirritating, are easily voided from the colon. I have seen a patient who, when upon a milk diet, passed small hard faeces with pain and distress, able under von Noorden's diet to empty his colon of bulky masses without trouble.

2. *Intestinal Antisepsis*.—The value of so-called intestinal antiseptics has always been a matter of argument. I have had bismuth, salol, beta-naphthol, cyllin, turpentine, and calomel, and of these calomel given in fractional doses continuously is the only one which has had apparent effect. The work of Metchnikoff upon the fauna and flora of the large intestine is well known, and he contends that by the introduction of milk curdled by a fresh culture of the lactic acid bacillus, an organism antagonistic to those inhabiting the great intestine is brought into the alimentary canal. I have had the opportunity of trying this method in 3 cases. In 2, two women, aged about 35, both suffering from mild colitis, with some abdominal pain and regular passage of mucus four or five times a day, the results were most satisfactory. Nothing definite could be seen with the sigmoidoscope. They were given half a pint daily of milk curdled by a pure culture of *Bacillus lactis*, and were placed upon von Noorden's diet. At the end of fourteen or fifteen days both patients were relieved of their symptoms. The third patient was an almost hopeless case of ulcerative sigmoiditis, who refused appendicostomy. A transient improvement in temperature and pulse were the only results of the treatment.

B.—Acute Ulcerative Colitis.

The treatment of these cases along purely medical lines seems to me unscientific and unsatisfactory. The ideal treatment would be to keep the colon empty and at rest. That, unfortunately, is impossible, for to stop all food by the mouth is to starve the patient and reduce his power of resistance. To feed him by the rectum is to irritate and stimulate the diseased part. It is impossible to prevent the entry of gastric, hepatic, and pancreatic secretions, and the constant evacuation of mucus and blood precludes the possibility of resting the colon. By the operation of appendicostomy, however, the large intestine can be completely emptied once or twice daily, and mild medicinal lotions can be introduced into the whole length of the great gut. Moreover, by the removal of the toxic secretions of the diseased mucosa auto-intoxication is in no small measure prevented.

Dr. W. Murrell,¹⁸ in the *Lancet* of March 12th, 1904, reported 5 cases of acute ulcerative colitis at the Westminster Hospital as follows:

- Males 3. Average age 25.6 years.
- Females 2. Average age 35.5 years.
- Deaths 4. Average length of illness six months.
- Recovery 1. Length of illness ten months.

These patients were treated upon medicinal lines, and they one and all showed similar symptoms: Temperature 100° to 102° F., pulse 120 to 140, and ten to thirty motions a day, with abdominal pain and tenderness, accompanied by progressive weakness. In the course of treatment the following drugs were used: Opium and morphine in all forms, bismuth carbonate, lead acetate, perchloride of iron, beta-naphthol, salol, perchloride of mercury, ipecacuanha, and formaldehyde by mouth, and rectal injections of silver nitrate. In one case an appendicostomy was attempted and found impossible owing to adhesions, so that an enterostomy was done. This was, however, only undertaken after an illness of eleven months, when the patient was extremely weak.

On the other hand, Mr. Holton C. Curl¹⁹ reported 11 cases of dysenteric colitis in which either an appendicostomy or a caecostomy had been performed early, with 8 recoveries and 3 deaths; 2 of the fatal cases had extensive ulceration associated with nephritis, whilst the third was moribund when the operation was performed.

I should like to mention a fatal case which I had under my care at St. Mary's Hospital last year, because I now feel that, had appendicostomy been performed early, the result would have been different:

A woman, aged 60, was admitted with typical symptoms of acute ulcerative colitis. The temperature was intermittent, with an excursion of 3 to 4 degrees. The pulse remained above 100 continuously. She passed blood and mucus mixed with faecal material ten to twelve times a day. Intestinal antiseptics of various kinds were tried by the mouth, and rectal irrigation with various lotions. There was little or no improvement, and after an illness of two to three months the patient suddenly developed symptoms of general peritonitis and died within forty-eight hours. *Post mortem* the peritoneum was found bathed in pus, and a perforation discovered just below the hepatic flexure of the colon. There was deep extensive ulceration of the colon, which had perforated at the point mentioned.

C.—Chronic Ulcerative Colitis.

It is for this condition that the operation of appendicostomy is most useful, whether a sequela to acute ulcerative

colitis, or to chronic constipation coupled with the ingestion of irritating drugs, matters not. The symptoms may be severe or slight, being those of excessive mucus secretion from the large gut, the mucoid evacuations being possibly stained with blood, progressive but slow loss of weight, and pain and tenderness in the region of the great intestine, especially over the sigmoid flexure. Sigmoidoscopic examination usually shows one of the following conditions:

1. Superficial ulceration without destruction of the submucous tissue.
2. Discrete punctate ulcers in which the submucous tissue is involved.
3. Large irregular serpiginous ulceration with destruction of submucous coats.

The frequent calls to stool, the abdominal discomfort, the passage of blood by the rectum, the failure of medicinal treatment, all tend to reduce the patient to a state of neurasthenia and chronic invalidism. Appendicostomy by completely clearing the great gut daily, removing the excess of mucus, and leaving a medicated lotion in the colon, tends to that rest and cleanliness which is essential for healing.

I have been able to find records of 10 cases of chronic ulcerative colitis for which the operation of appendicostomy has been performed, including two which came under my own personal observation.

CASE I.

A fish hawk, aged 25, who had been a soldier, and had had two attacks of acute dysentery—in Africa in 1900, and in India in 1906—complained of six to eight motions of blood and slime daily, without pain, and no marked emaciation. His general condition was excellent: the sigmoidoscope showed considerable oedema of the submucous tissue, with chronic inflammation of the mucous membrane and superficial ulceration, especially marked on places exposed to friction, such as the edges of the rectal folds.

Appendicostomy was performed on July 23rd, 1907, by Mr. Swinford Edwards. Four days later irrigation was started, 6 pints of weak boracic lotion being slowly allowed to flow through the catheter into the caecum. A moderate-sized vulcanite tube was passed through the sphincter for about 3 in. The inflow was regulated so as not to allow of too great distension, and abdominal massage along the course of the great gut employed. After about six minutes the lotion began to flow from the rectum, bringing with it fragments of faeces. Before the outflow began and when the patient's abdomen was distended and tense the catheter was removed from the appendix, and, though no protection against backflow was taken, there was no trace of leakage, the muscular coat and the valve of Gerlach proving competent to prevent any escape of the lotion. After four days the lotion was changed to one of sodium bicarbonate, gr. x ad 5j, and this was changed after two days more to one of protargol, gr. iv ad 1 pint. The patient remained in hospital one month, and was taught to conduct the irrigation himself. It was found that after a few days the rectal tube was unnecessary, the patient evacuating the lotion as soon as the colon became moderately distended. He was sent home with an abdominal belt fitted with a flat, thin pad—a contrivance found to be unnecessary in subsequent cases.

After two months' self-irrigation daily with 6 pints of protargol lotion, he was again examined with the sigmoidoscope on October 29th, 1907. The mucous membrane was found to be slightly inflamed, and there was still some oedema of the submucous tissue, but no sign of ulceration. The patient himself stated that he was perfectly comfortable and at work; he occupied himself for half an hour every morning with the irrigation, and after that had no further trouble during the day. Throughout his diet was his usual one, and the only other treatment was the administration of gr. ʒ of calomel three times daily while in hospital.

CASE II.

A man aged 42, under the care of Mr. Rawlings, of St. Bartholomew's Hospital, to whom I am indebted for permission to quote the case, presented similar symptoms, except that the diarrhoea was more marked, there being about nineteen or twenty evacuations daily, and that the emaciation and weakness were severe.

Appendicostomy was performed, and the colon irrigated daily with astringent lotions. After two months the patient was free from trouble, continuing the irrigations himself, and being free from any evacuation after the washing was completed. He was delighted with the result, and had put on weight rapidly.

CASE III.

Dr. Robert F. Weir²⁰ performed appendicostomy for ulcerative colitis in 1902. This is the first reported case of this operation.

CASE IV.

Mr. Stretton,²¹ of Kidderminster, reported a case in 1906.

CASE V.

Mr. H. M. W. Gray,²² of Aberdeen, reported one case in 1904, with satisfactory result.

CASE VI.

Dr. Robert H. W. Dawbarn²² reported one case, resulting in cure, in 1905. The lotions used for irrigation were 10 pints of 1:1000 solution of potassium permanganate, alternating with a similar quantity of normal saline solution.

CASE VII.

Mr. Hutchinson,²³ of London, reported a case resulting in cure in 1905.

CASE VIII.

Sir William Bennett²⁴ recorded a satisfactory case in 1905.

CASE IX.

Mr. Stanmore Bishop,²⁵ of Manchester, reported a satisfactory case in 1905.

CASE X.

A man, aged 42, under the care of Dr. Foxwell at the Queen's Hospital, Birmingham, who had been ill for three months, complained of pain, diarrhoea of blood-stained mucus. His serum clumped a culture of Shiga's bacillus in a dilution of 1 in 40, but not 1 in 100.

He was operated upon on March 16th, 1908, and washing out was commenced ten days later. Within a week his condition was improving, the pain was absent, and the diarrhoea less. A month later he was well and having a single well-formed motion daily.

D.—Chronic Simple Colitis.

Under this heading I place those cases in which there is a passage of mucus with the faeces and independently, but in which no sign of ulceration can be seen with the sigmoidoscope. I include also those cases of colitis with casts in which I can find no record of sigmoidoscopy. I do not consider the passage of casts a sign of simple chronic colitis, for I am convinced that casts may occur in all forms of colitis, and it is only by the use of the sigmoidoscope that a definite statement as to the condition of the mucosa can be made. There seems to be no satisfactory explanation why casts should form in some cases any more than there is any reason given for the fact that in some patients the mucus secreted by an inflamed pharynx should take on a membranous appearance. A hypertrophic form of colitis with abundant mucus can be recognized by the sigmoidoscope, and I very tentatively suggest that colitis with casts may be of the nature of an atrophic form.

I have collected the following cases, the first two coming under my own care when house-surgeon at St. Mark's Hospital:

CASE XI.

A woman, aged 38, married, two children. Abdominal examination revealed some tenderness over the sigmoid, and possibility of palpating both kidneys. The sigmoidoscope showed an inflamed mucosa with abundant secretion of mucus. Mucous evacuations nine to ten daily. No blood passed per rectum. Loss of weight.

Appendicostomy was decided upon because the patient had received some months' treatment by drugs and rectal injections without avail. The operation was performed on June 18th, 1907, by Mr. Swinford Edwards. The treatment and irrigations used were similar to those in Case I. The patient was discharged on July 15th, 1907, and self-irrigation conducted until October 29th, when she was again examined with the sigmoidoscope. The bowel was found healthy, with no inflammation or excess of mucus. She stated that she was quite well, had increased in weight, and found no inconvenience either from the daily wash-out or the presence of the fistula.

CASE XII.

A man, aged 35, was admitted for perianal papillomata, which were removed. For two previous years he had been treated with rectal injections, for mucous diarrhoea, with four to five evacuations daily, associated with some pruritus ani and the growth of the papillomata. There had been some blood with the mucus at times. Sigmoidoscopy showed chronic inflammation of mucosa with granular patches.

Appendicostomy was performed by Mr. L. Mummery on September 10th, 1907. Treatment was similar to that of the previous case. After one month the patient had lost the slight abdominal pain present before operation, and after his daily wash-out had no further trouble throughout the day. I have no record of a sigmoidoscopic examination after the operation.

CASE XIII.

Gray²⁶ of Aberdeen in 1904 reported a case of a woman with frequent evacuations and passage of casts. Appendicostomy produced a cure in four weeks. There was a slight tendency to relapse twenty months later.

CASE XIV.

Morley Willis²⁷ in 1906 reported a case of colitis with mucus but no casts in a woman aged 32. Appendicostomy produced much improvement in one month.

CASE XV.

Donald Armour²⁸ reported in 1908 a case of colitis with casts satisfactorily treated by appendicostomy.

CASE XVI.

Moynihan²⁹ recorded a case of colitis with casts cured by appendicostomy in 1905.

I would make an urgent plea for the more general and regular use of the electric sigmoidoscope. I am convinced, not only of its utility, but also of the necessity and advantage of its use in all cases presenting the symptoms of colitis in however slight a form. Apart from the accurate diagnosis of the cause of the mucous discharge, it has been the means of obtaining information of great value both to the patient and surgeon. It is well known that certain forms of carcinoma recti produce no symptoms beyond a mucous discharge, possibly blood-stained, and a vague sense of uneasiness in the lower abdomen—an aggregation of signs common to several forms of colitis. Should the growth be situated near the junction of sigmoid and rectum or opposite the third piece of the sacrum, it cannot be felt either with a finger in the rectum or by abdominal examination. Cantlie³⁰ has recently shown that the point of junction of the pelvic colon with the rectum is marked by a narrowing of the lumen of the gut, and by a thickening of the muscular coat approximating to a sphincter, to which he has given the name "sigmo-rectal pylorus." This constriction, and the increased friction and trauma produced thereby, may be an explanation for the occurrence of carcinomata at this site.

I can call to mind 3 such cases admitted to St. Mark's Hospital last year—cases which presented symptoms suggestive of ulcerative colitis, discharge of blood and mucus, and slight abdominal discomfort attended with little or no difficulty of defaecation. In all these cases the sigmoidoscopic examination revealed the presence of a malignant growth at the position mentioned, although the carcinomata could not be reached by bimanual examination. These 3 cases had been under medicinal treatment for colitis for some time.

The discharge of excessive mucus, with or without blood, from the rectum, is not a disease but a symptom, and it is only in accordance with modern surgical exactness to endeavour in all cases to diagnose accurately the pathological condition producing such symptoms.

Mr. L. Mummery,³¹ in a recent paper, published 36 cases, all of which had symptoms of colitis; mucus being present in the stools in all, blood in 22 cases, casts in 8 cases, intestinal sand in 2, and enterospasm in 1 case. The use of the sigmoidoscope in all 36 cases revealed the following conditions:

- 11 cases showed inflammation of the mucosa without ulceration;
- 7 cases showed ulceration;
- 7 cases showed malignant disease;
- 3 cases showed inflammation with constriction due to peritoneal adhesions;
- 1 case showed inflammation due to the pressure of a retroverted uterus;
- 1 case showed inflammation with presence of a polypus high up;
- 6 showed nothing to account for symptoms.

Beck³² in 500 cases of chronic colitis, found inflammatory lesions in the colon in 394, or 78.8 per cent.

APPENDICOSTOMY FOR CHRONIC CONSTIPATION.

The question of surgical interference in cases of protracted constipation is one which crops up periodically, mainly on account of the work of Mr. Arbuthnot Lane. So much depends upon what degree of derangement of function is understood by the words "chronic" or "protracted." Mr. Lane does not lay down any clear definition of what he considers sufficient indication for operation. He talks of the auto-intoxication due to coprostasis, which surely is an elastic term, including the headache following a day's irregularity or the profound toxæmia seen in patients who allow weeks to elapse without relieving their abused colon.

Ordinary chronic constipation which necessitates the regular use of aperients, enemata or suppositories, is amenable to medical and hygienic treatment, but there are some few protracted cases in which perhaps fourteen days to three weeks may elapse between the acts of defaecation, in which the usual medicinal remedies produce no other result than abdominal distension and discomfort, and in which the early signs of irritation to the mucosa are manifest, where surgical interference is fully justified.

If the surgeon decides to operate, he may perform (1) ileo-sigmoidostomy, (2) ileo-sigmoidostomy with colectomy,

(3) appendicectomy with liberation of adhesions, (4) appendicostomy, (5) valvotomy.

The first two procedures are associated with the name of Mr. Lane, who has, however, practically abandoned ileo-sigmoidostomy alone for the more formidable operation of removing the great gut as far as the lower portion of the sigmoid flexure.

An analysis of Mr. Lane's recently published results³⁰ shows the following:

Total number of cases
Total number of operations
Average number of operation
One patient underwent	9 operations	...
One	5	...
One	5	...
Three patients	4	...
Six	3	...
Two	2	...

All these operations were not performed by Mr. Lane himself, some having been done prior to Mr. Lane's treatment. Most, however, were for adhesions or some manifestation of enteropneumosis.

Results.

Number of cases	...	39
Satisfactory recoveries	...	19, or 50 per cent.
Imperfect recoveries, patients still having intestinal symptoms or needing enemata, etc.	...	9, or 23 per cent.
Bad results	...	2, or 4 per cent.
Deaths (total, 9, or 23 per cent.):
Immediate	...	7, or 17.9 per cent.
Remote	...	2, or 5 per cent.

Immediate Results.

Immediate, 7—death occurring at an average of 8.7 days after operation:

1. Suppuration in wound with perforation of intestine.
2. Shock and vomiting.
3. Shock.
4. Bronchitis.
5. General peritonitis.
6. Intestinal obstruction.
7. Perforation of gastric ulcer.

Remote, 2:

1. Complete relapse and death after one year.
2. Acute obstruction (no autopsy) after seven months.

The question to decide is whether a palliative operation, which in such skilled hands yields a total death rate of 23 per cent. of which 18 per cent. is accounted for by the immediate results of surgical interference, is justifiable, especially when only 50 per cent. of cases so treated are given satisfactory relief.

To amputate the appendix and sever adhesions in a case of protracted constipation is too much of a shot in the dark. The appendix may be, and commonly is, the seat of extensive adhesions, the division of which with any other similar constricting bands may relieve the patient completely, but there can be no certainty that such will be the case. On the other hand, by utilizing the appendix to make a path whereby the large intestine can be reached for lavage or direct medication is surgically sound.

This method renders it possible to destroy any adhesions present, whilst at the same time the appendix ceases to be a dangerous possession, and is put to a valuable use. The procedure after the operation is to empty the colon by douches, preceded if necessary by small injections of olive oil to soften the faecal masses. I can only quote one case in which this method has been tried, but with a most satisfactory result.

Murray³¹ in 1905 first suggested appendicostomy for protracted constipation, and later in the same year Keetley³² performed the operation. His case was that of a young girl aged 15, who was subject to most obstinate coprostasis, which medicinal treatment failed to relieve. When seen by Mr. Keetley the bowels had not been emptied for fourteen days, and the patient showed signs of considerable toxæmia. Appendicostomy was done; the transverse colon, loaded with faecal masses, was found to descend below the umbilicus. After the introduction of warm olive oil, followed by a large injection through the appendix of a warm solution of magnesium sulphate, the patient passed with considerable pain and difficulty a great quantity of faecal material by the rectum. After this initial evacuation the daily introduction into the caecum of about 5x of warm magnesium sulphate solution, and later of warm water alone, enabled the patient to have an easy and normal motion. The appendical opening gave no trouble, and the transverse colon became gradually less pendulous. The patient would not, up to the time the case was reported, allow the opening to be closed, so that it is not possible to say if the daily lavage of the colon had a curative effect.

Inasmuch as the ptosis of the transverse colon tended to remedy itself, and as the regular distension and evacuation of the colon would constitute a sort of physical exercise for the gut, there are grounds for the opinion that the operation may have had a curative effect upon the lethargic intestinal muscles.

Valvotomy.

The procedure of incising the valves of Houston for chronic constipation comes to us from America. It has not been proven how far these plications produce arrest of faeces. The fact that they do not exist in quadrupeds seems to suggest that they have some function associated with the erect posture. It is possible that in a few cases one or more of the valves may be hypertrophied, so that good results may follow division.

Given, therefore, a case of protracted and obstinate constipation, for which surgical measures are indicated, we have the choice of two methods—one, ileo-sigmoidostomy, which in skilled hands gives a death-rate of 23 per cent., or appendicostomy, which our knowledge of appendicectomy leads us to believe would yield a death-rate of under 1 per cent.

APPENDICOSTOMY FOR DRAINAGE OF THE CAECUM AND RELIEF OF ABDOMINAL DISTENSION.

The use of this operation in cases of distension depends so much upon the exigencies of the moment that it is not possible to lay down any rules or indications. I have collected 3 cases, however, which indicate its scope in various abdominal conditions.

The suggestion that the appendix might be used as a spout for the relief of intestinal obstruction was first made by Keetley in 1894,³³ and put to the test by that surgeon in 1906.³⁴

The case was one of carcinoma of the greater curvature of the stomach, involving the transverse colon and causing obstruction therein. Appendicostomy was performed, and a few days later the lumen was gradually and successfully dilated until it admitted a No. 4 rectal tube. Through this the intestinal contents drained well, the colon below the obstruction being emptied by enemata. Later the gastric carcinoma produced obstruction of the pylorus with the usual signs of stenosis and dilatation of the stomach. Jejunostomy was then performed, through which the patient lived for three and a half months, being fed directly into the jejunum and having the bowels evacuated through the appendix. Death was due to the progressive malignant cachexia, but was unaccompanied by the distress of either gastric dilatation or intestinal obstruction.

Jacobson and Rowlands³⁵ mention a case of volvulus of the caecum operated on by Mr. Mansell, in which after unfolding the volvulus he performed appendicostomy, the result being that he effectually anchored the caecum and so prevented a recurrence, and also was able to clear the large intestine of faeces for the introduction of hot saline to combat shock.

Mr. Keetley³⁶ in 1905 operated upon a child aged a year and ten months for intussusception of the ileo-caecal variety. After reduction he performed appendicostomy, the advantages he claimed for the procedure being: (1) Evacuation of bowels. (2) Prevention of recurrence, (3) rest given to caecum, (4) facility of giving saline fluid.

APPENDICOSTOMY FOR NUTRITIVE PURPOSES.

It has been suggested that this operation might be performed and the opening utilized for feeding. The unsatisfactory results of prolonged rectal feeding are so well known that the suggestion seems worthy of consideration. The operation *per se* is practically free from danger, and allows nourishing fluids to be passed into the colon, whence there is considerable absorption. It can at least be safely assumed that the amount of nutriment taken into the circulation would be greater than in the case of rectal enemata. This is borne out by the experiments of Goodard,³⁷ who showed that 10 per cent. of fat ingested is absorbed in the great intestine. The cases for which such treatment would be suitable are mainly those of ulceration or new growth of the stomach in which rest to that viscus is indicated. Since the patient has to undergo an operation, it would seem more reasonable at once to perform a gastro-enterostomy and not attempt the purely palliative measure.

It is possible, however, that there are cases in which appendicostomy for purely nutritive purposes would be useful, such as those in which, either through perigastric adhesions or previous operative measures, gastro-enterostomy is not possible, and those of profuse haematemesis, in which surgical interference with the stomach itself is dangerous.

APPENDICOSTOMY TO PERMIT DIRECT MEDICATION OF THE LOWER ILEUM.

It has been suggested by Ewart¹ that use might be made of this operation to reach the lower portion of the ileum. He proposes it for the surgical treatment of typhoid fever. He was able, both in the cadaver and in the living subject, to pass a catheter through the ileo-caecal valve for some 6 to 8 in., and so to irrigate the bowel. He used a Jacques catheter mounted on a stilette of soft pliable copper, bent at a suitable angle.

I can find no record of this suggestion being put into practice, and how far it is justifiable I do not know. Since the typhoid bacillus is, during the course of enteric fever, present in the mesenteric glands, the spleen and other viscera, it seems unlikely that the most thorough irrigation of the ileum would do much to lessen the toxæmia. Possibly healing of the ulcers might be hastened, and any tendency to perforation diminished.

CONCLUSION.

The foregoing are the uses to which this operation has been or it has been suggested might be put.

The use of appendicostomy for colitis was preceded by the operations of right inguinal colostomy and caecostomy. Right inguinal colostomy is not easy to perform; it is difficult to close satisfactorily, and places the patient in a most unenviable position. The constant flow of fluid, irritating faeces over the surface of the wound and surrounding skin, soon to become excoriated and sore, is most distressing, requires the constant attention of a nurse, and prolonged sojourn in bed. It is true that by this operation the faecal stream is entirely directed away from the colon, which is thereby given greater rest; but the complete daily evacuation and irrigation possible with appendicostomy seems to be sufficient for the purpose. Cases of colitis have a well-known tendency to relapse, and it is not easy to decide when to close the colostomy wound, for, having once closed it, the opening is not readily re-established. Thus, Hale White and Golding-Bird reported a case of colitis treated by this operation, which relapsed two years after the closure of the colostomy opening. With appendicostomy, however, if, after treatment has been stopped, the opening be allowed to stenose naturally, which it will readily do, it gives no trouble, and can be dilated at a later date with suitable bougies, presence of the mucous membrane preventing complete closure of the fistulous tract. For very similar reasons the operation of caecostomy has, in my opinion, been superseded by appendicostomy. Caecostomy is more difficult to perform and more difficult to close. There is practically always some leakage of faeces, and the result for the patient is unsatisfactory. When done to divert the intestinal contents from the colon the result is imperfect, since the diversion is incomplete.

It is interesting to note that the first use of the appendix for irrigation purposes was the result of an unlooked-for incident. Weir was about to perform a caecostomy, but in opening the abdomen the appendix presented itself so opportunely that he utilized it in the way stated.

I have quoted 20 cases in which the operation of appendicostomy has been performed, 4 of which have come under my personal notice and supervision. Summarized, they are as follows:

For ulcerative chronic colitis	10
For simple chronic colitis	6
For protracted constipation	1
For other abdominal conditions	3

This does not take into account the cases reported by Curl, for I was unable to determine in how many he performed appendicostomy and in how many caecostomy.

In all the cases the operation was successfully performed, and was of marked benefit to the patient. In the cases of colitis the following results were obtained:

For ulcerative colitis:	
Total cases	10
Cures obtained	9
For simple chronic colitis with and without passage of casts:	
Total cases	6
Cures obtained	3
Much improvement after one month	1
Apparent cure in four weeks with slight tendency to relapse twenty months later	1
Cure after six weeks, no subsequent history	1

Of untoward events following operation I have found no report. In my own experience of the procedure I met with three small misadventures which may be of interest:

1. Stitch suppuration in those cases in which the appendix was opened on the table.
2. Through the carelessness of a nurse a catheter was allowed to slip into the caecum. It was passed per rectum without any discomfort within twelve hours.
3. One patient, whose colon was washed out daily with six pints of boric acid lotion for seven days, developed signs of poisoning. She complained of severe frontal headache, vomiting, a slow pulse of about 58, and an eruption over the trunk and limbs. The rash consisted of small discrete papules of a light pink tint. On discontinuing the boric acid lotion and washing out the colon with sterilized water the symptoms abated, and disappeared in twenty-four hours.

LEUCOCYTOSIS IN APPENDICITIS.

By GEORGE MITCHELL, M.B., Ch.B., L.M.,

LATE HOUSE-SURGEON, ABERDEEN ROYAL INFIRMARY.

WHILE acting as house-surgeon in Mr. Riddell's wards in the Aberdeen Royal Infirmary I had the opportunity of examining the blood of a large number of patients suffering from appendicitis. The results of my early observations seemed so valuable that I continued the examinations during the whole year of office.

The behaviour of the leucocytes in most cases gives a sure index both of the intensity of the morbid irritant and of the individual's powers of resistance. Regarded in this light, and considered along with other clinical data, it is of great practical value in many cases. If taken by itself as a pathognomonic sign it would frequently be found to be as misleading as any other individual symptom.

The great drawback to such a method of clinical investigation in urgent cases is the fact that an apparatus and time are necessary; hence it is not so applicable to cases outside hospital practice. Reliable results can, however, be got after a short experience, provided a reasonable amount of care is exercised. On several occasions I have seen the blood of a patient examined by several different men, and the results in most cases were found to be practically similar.

This statement does not apply so accurately to the absolute count as to the differential count. Variations in the result of the absolute count are much more frequently encountered, but I am quite prepared to believe that probably such discrepancies are due to faulty technique.

ABSOLUTE COUNT.

Accurate information is got from studying both the absolute and the differential counts. In practically all cases of appendicitis and of acute abdominal or pelvic inflammation going on to pus formation or necrosis there is an increase in the number of leucocytes; and, speaking generally, it may be laid down that the greater the increase the more severe the nature of the lesion and the graver the prognosis. The great exception to this is to be found in severe cases of very sudden onset, especially in an individual whose powers of resistance are very slight. The reaction of the leucocytes depends mostly on the severity of the morbid condition and on the resisting powers of the individual.

In gangrenous and suppurative appendicitis, and in other acute suppurative abdominal conditions, the absolute

count is generally over 20,000, but cases in urgent need of operation with an absolute count of considerably under 20,000 are so numerous that one feels rather sceptical of the old rule to regard cases with a leucocyte count above 20,000 as indicative of pus formation or necrosis, and those under 20,000 as catarrhal.

It is of more service to know the rate at which the leucocytosis is increasing than to know the actual number of leucocytes per cubic millimetre in a given case. An increasing leucocytosis means that the individual is attempting to battle with the toxins eliminated from the morbid area, while if the leucocyte count rises above that indicating pus formation or gangrene, and keeps on rising rapidly, it shows that virulent poison is being freely circulated in the system, which may gain the upper hand at any moment if operation is not resorted to. Cases of acute appendicular abscess are quite common with a leucocytosis of 15,000 to 17,000. As a rule, one meets with a higher leucocytosis in gangrenous appendicitis than in abscess formation.

Most cases of gangrenous appendicitis ending in recovery have as a rule a high absolute count, many of them from 30,000 to 40,000, but, on the other hand, the leucocyte count may be as low as 15,000.

I think it is generally accepted that cases in which the general symptoms are severe and the absolute count low frequently die. I can recall two cases of perforated gangrenous appendicitis with diffuse general peritonitis, both of which had a leucocyte count of 12,000. The symptoms were extreme in both, and the patients died within twelve hours after operation.

In cases with very sudden onset, accompanied by a severe amount of shock, there may be little or no increase in the number of leucocytes; but if the individual reacts from the shock the leucocytes become increased and rise above normal, while if the reaction fails the leucocytes do not rise.

The variation in the leucocyte count is of great service in forming a correct opinion as to when operation should be performed in cases of appendicular abscess or pelvic abscess from other cause.

It would appear that if the leucocytosis is not increasing to any appreciable extent in cases in which there are clinical signs of abscess formation, it is safe to conclude that the abscess is becoming "walled off" by adhesions, and so operation can be safely postponed till the abscess has been thoroughly shut off from the general peritoneal cavity. The size of the leucocytes varies very much in different cases and in the same case at different times, but such variation is said to be of comparatively little significance. A low count means one of three conditions:

1. A mild case.
2. A very severe case.
3. An abscess thoroughly walled off (Cabot).

DIFFERENTIAL COUNT.

While very valuable information can be obtained from the absolute count, that obtained from the differential count is even more reliable. The most important changes in the differential count are the great increase in the percentage of polymuclear cells and the diminution in the percentage of lymphocytes and eosinophiles.

Most authorities agree that the average percentage of polymuclear cells in the healthy subject varies from 65 to 72 per cent. (62 to 70 per cent., Cabot). In acute inflammation the percentage of polymuclear cells is always found to be increased.

In the cases of acute appendicitis going on to gangrene or pus formation that came under my observation the percentage of polymuclear cells varied from 79 to 90 per cent., and was generally higher in cases of gangrene than in those of abscess formation. It was also found to be higher in those presenting evidences of severe toxæmia. The highest count was 90.5 per cent. in a case of gangrenous appendicitis with general peritonitis, followed by death.

The ratio between the increase in the absolute number of leucocytes and the increased percentage of polymuclear cells in the greater number of my counts was about 1,000 to 1.5 per cent.—that is to say, taking the normal number of leucocytes to be 10,000 per c.mm. and the percentage of polymuclear cells as 72 per cent., then for every 1,000 of increase in the absolute count there was a corresponding increase of 1.5 per cent. in the polymuclear cells. All cases

that ended in recovery after operation had shown a marked increase both in the total number of leucocytes and in the percentage of polymuclear cells (before operation), while the two cases suffering from perforated gangrenous appendicitis with general peritonitis, already referred to, had 88 per cent. and 90.5 per cent. of polymuclear cells respectively, with only 12,000 of an absolute count in both cases. I had the opportunity of examining the blood only in these two fatal cases, but the results of these point to the fact that in severe cases a low absolute count is frequently got, while the percentage of polymuclear cells is generally high.

TEMPERATURE AND LEUCOCYTOSIS.

The relation of temperature to leucocytosis does not seem to give reliable information, as cases are seen with grave clinical symptoms and high blood counts with little or no temperature; but, on the other hand, there are many cases showing an increase in the number of white cells, accompanied by pyrexia, which, like the number of leucocytes, varies very rapidly, according to conditions existing at the site of the pathological lesion. An illustration of this is afforded by the following case of appendicular abscess with retention after operation. The blood was examined immediately before operation and daily after operation:

On admission:			
Absolute count	19,500.
Differential:			
Polynuclears	84.5 per cent.
Lymphocytes	13.4 "
Eosinophiles	0.3 "
Mast cells	—
Large hyaline	1.5 "
Temperature 102.6°.			
First day after operation:			
Absolute count	19,000
Polynuclears	78 per cent.
Lymphocytes	20.5 "
Eosinophiles	0.5 "
Mast cells	—
Large hyaline	1 "
Temperature, 100.4°.			
Free discharge of pus.			
Second day after operation:			
Absolute count	17,000
Polynuclears	62.3 per cent.
Lymphocytes	36.3 "
Eosinophiles	0.3 "
Mast cells	—
Large hyaline	1 "
Temperature, 99.8°.			
Free discharge of pus.			
Third day after operation:			
Absolute count	20,000
Differential:			
Polynuclears	76 per cent.
Lymphocytes	22.5 "
Eosinophiles	—
Mast cells	—
Large hyaline	1 "
Temperature, 102.5°			
Discharge of pus much less.			
Fourth day after operation:			
Absolute count	16,000
Differential:			
Polynuclears	82 per cent.
Lymphocytes	16.5 "
Eosinophiles	0.5 "
Mast cells	—
Large hyaline	1 "
Temperature, 103°.			
Discharge almost ceased.			
Fifth day after operation.			
Absolute count	16,200
Differential:			
Polynuclears	77.3 per cent.
Lymphocytes	20.3 "
Eosinophiles	1.0 "
Mast cells	—
Large hyaline	1 "
Temperature 99°.			
A few hours after the taking of the previous count a large quantity of pus was evacuated from the wound.			
Sixth day after operation.			
Absolute count	10,800
Differential:			
Polynuclears	75.5 per cent.
Lymphocytes	21 "
Eosinophiles	0.5 "
Mast cells	—
Large hyaline	2.5 "
Temperature 98.6°.			
Free discharge of pus, and no subsequent retention.			

INCREASE OF LYMPHOCYTOSIS DURING RECOVERY.

While making examinations of the blood of patients who had been operated upon for appendicular abscess it was observed in many cases that, very soon after the percentage of polynuclear cells and lymphocytes had returned to normal, the percentage of lymphocytes became increased. In most cases the increase was absolute, while in others it was only relative.

The following count is that of a case of appendicular abscess sixteen days after operation, where the discharge of pus had almost ceased:

Absolute count	10,000
Differential:			
Polynuclears	57.7 per cent.
Lymphocytes	36.5 "
Eosinophiles	2.0 "
Mast cells	0.5 "
Large hyaline	2.5 "

Most of the cases that showed lymphocytosis continued to do so up till the time of discharge from hospital, so that I could not ascertain how long the condition persisted. The greater number of those cases appeared to be in fairly good health; but perhaps the condition of the blood may be explained by the low condition of the patients after a severe attack of appendicitis.

SYPHILITIC LEUCODERMA AND THE PIGMENTARY SYPHILIDE.

By SIR JONATHAN HUTCHINSON, F.R.S.,
CONSULTING SURGEON, LONDON HOSPITAL.

"DAFFLED" is the term by which to describe the state of the skin in syphilitic leucoderma. A glance at the appended illustration will show what is meant by it.

Dappling may be studied on the coat of a grey horse or a fallow deer, and with especial interest on that of the giraffe. It consists of the location of isolated patches of a tint different from the ground on which they are placed. The patches may be small or so large as to cover almost the whole of the ground, and thus make it difficult to recognize that they ever were merely patches. In the giraffe of South Africa the skin is a brown bay, but almost angular areas are mapped out by lines of yellowish-white, whilst in the giraffe of Northern Africa the lines of light colour have widened out until only islands of brown remain. Yet the two animals are probably not distinct species. In the dappled horse the arrangement of colour is reversed, it is the patches (or spaces) which are pale and the interspaces (or ground) which are of darker tint. I have felt it necessary to state these facts in order to make comprehensible my own theory of syphilitic leucoderma. In the domesticated horse it is only certain individuals which show a marked tendency to dapple in any conspicuous degree. We must suppose, however, that the potential endowment exists in all. Many, perhaps all, dappled horses become whiter—that is, less dappled—as age advances. The young of many animals show in extreme youth a speckling, spotting or streaking of their skins which they lose when adolescent.

My theory as to syphilitic leucoderma is that the human skin is in many persons latently dappled, and that the condition becomes obvious under certain states of disturbed pigment function of some of which the spirillum of syphilis may be the cause.

The two letters which appeared in the *JOURNAL* of November 28th, 1908, p. 1650, warn me to be more careful as to making negative suggestions. The fear of the criticism of men better read and enjoying better memories than myself is now before my eyes. It must suffice, therefore, to say that if any portrait or detailed description of leucoderma syphiliticum in a negro or in one of the dark races has been published, I should be very thankful to be referred to the work in which it occurs. Such records, if they exist (and probably they do), would be most helpful to us in the endeavour to interpret the phenomena of this interesting condition.

In my last letter* I left the description of our own museum portraits unfinished. I will now, with your permission, attempt to complete it. Before doing so, however, it may be well that I should say a few apologetic words in reference to the letters from Dr. Pernet and Mr. Ernest Lane, which have appeared in the *JOURNAL* of November 28th, 1908, p. 1650.

These gentlemen point out, and with, I regret to say, some truth, that I have much understated the case as regards the amount of attention which has been given to this subject by English authors. I was wishful to show that the condition is one which is probably far more frequent on the Continent than it is with us, and had no wish to disparage or neglect our own literature. I admit that the expressions I used were too strongly put, and they can at first sight be explained away only by pleading either ignorance or forgetfulness. I hope my friends will allow me to plead guilty to their accusation under the head which they may deem the most pardonable. My words have, however, been taken to imply much more than they were intended to. They were dictated when I was standing on the Museum floor with a display of six portraits of leucoderma syphiliticum before me from Continental sources, and not a single one from an English source; and although I was aware that most of our systematic works, whether on syphilis or dermatology, had mentioned it, I had forgotten that any of their authors had recorded original facts, and thought that most had derived their information from foreign sources. I felt sure that, although the condition is one which invites alike the camera and the artist's brush, no English portrait of it had appeared. Whilst my letter was in the printer's hands my memory was fortunately reinforced in reference to the portrait given in the new *System of Syphilis*, and by the indulgence of the Editor I was allowed to squeeze in at the last moment a line of postscript in order to show that I knew of it. Now, of this portrait I had been previously quite cognizant, and had pointed it out with much commendation to

Fig. 1.—The arrangement of leucoderma syphiliticum on neck of a girl. Copied by permission from Chotzen's Atlas.

some friends, but I had not then been able to display it with the others in my collection (it has since been added), and at the time I wrote it had absolutely escaped my recollection. It was, in fact, brought back to my recognition by one of my friends, to whom I had myself shown it a fortnight

* *BRITISH MEDICAL JOURNAL*, November 21st, 1908, p. 1592.

previously. Even when I added the postscript I did not know of the existence of any letterpress description of it. I have since found out and read the able and interesting article contributed by Mr. Arthur Shillitoe to this most important work on this very subject.

So far as my references to modern works during the past week have extended, I should have been inclined almost to repeat my statement of belief that the condition is one which is rare in English practice, and has been but little studied either by dermatologists or writers on syphilis were it not for Mr. Shillitoe's article. Mr. Shillitoe has enjoyed in the department of the Lock Hospital devoted to women very exceptional opportunities for observation. The result is that he declares that a condition which most of us had supposed to be decidedly rare is really quite common. He actually found it in 75 per cent. of a series of syphilitic patients observed consecutively. The explanation is that in addition to having a splendid field to work over he made most painstaking search, using optical aid, and thus no doubt identified it where most of us would have failed to see it.

As I have said, were it not for this article I do not think that I should incline to make any apology to my friends your two correspondents. I find exceedingly little evidence that any of the brief statements in systematic works were written from personal observation. In more than one instance there are misstatements which prove that they were not. What I wrote as to the disease not having been observed or described did not mean that it had been omitted from textbooks, but that no original work had been recorded. Mr. Shillitoe's account, however, relieves our home literature from this charge, and seems to prove that the condition, if well looked for, is as common here as on the Continent and in America.† There remains, however, a fact which I cannot but

very much as to its degree of development, and that in a large majority of cases it may be very inconspicuous. As regards my own experience, although I have recognized a few ill-marked cases, I have certainly never seen conditions approaching in conspicuous peculiarity those shown in several Continental portraits. Had such come under my notice I should certainly have preserved a photograph or a water-colour portrait, and I have none. Some of my dermatological *confrères* may have done so and will now bring them to light, but as yet I have not heard of any.

I regret having been obliged to occupy so large a portion of your space in explanations of a somewhat personal character. The necessity has been laid upon me by the publication of your correspondents' somewhat impetuous letters. I had already promised to explain "next week," as regards Mr. Shillitoe, my wholly accidental omission; and had this been waited for, the necessity for anything further might probably have been anticipated. I will now gladly pass to the more congenial task of dealing with the subject itself. There are, perhaps, few topics which better exemplify the advantages of such a collection as that which we have now made at the Polytechnic Museum, and I would earnestly beg any who may be interested in leucoderma syphiliticum to do me the honour of an inspection of the collection. It will supply a good substratum of recorded and easily appreciated facts and will obviate important misconceptions which have found expression in some of our textbooks. The collection is by no means complete as regards all that has been published, but no pains will be spared to make it more so, and the loan of any drawings which may be

Fig. 2.—From the back of the neck of Neumann's portrait.

Fig. 3.—From the loin of the same.

still think implies something—that the affection has been widely discussed and well illustrated by portraits elsewhere, but has not until within the last few months claimed any detailed attention here; or been thought to be worthy of pictorial representation. If it could be made probable that there is great difference in the degree of prevalence in different races and different climes the fact might serve some purpose in our discussion as to its probable causes. For the present, however, with Mr. Shillitoe's statements before us, we must wait. We must note that this form of leucoderma is one which varies

Fig. 4.—From the back of the neck of one of Chotzen's portraits.

The suggestion is that the pale spots are normal, and the dark ground and the central "nuclei" abnormally pigmented. It is essential that the reader should recognize that there are no "spots" in any other sense than changes of tint. The conditions here shown have been purposely somewhat exaggerated, with the object of clearness.

entrusted to us will be most gladly welcomed. The following is a list of what we can offer for present inspection:

1. A coloured lithograph published by Pommier in 1881. It represents the neck and part of face of a young woman.†

† In reply to the question whether "pigmentary syphilis" or "syphilitic leucoderma" is the preferable term, it may be replied that both are needed. In a large proportion of cases of syphilis there is in the secondary stage some disturbance of pigment, and those in which the changes become conspicuous range themselves in two groups: those in which pigmentation alone is evident, and those in which leucodermic patches are present. No doubt the two are closely connected, and it is assumed, but by no means proved, that the one may precede the other. Clinical convenience, however, requires that we should recognize each by its appropriate name. The omission to do so has led to considerable apparent contradiction in the statements of authors. Those who consider the condition common are dealing with the pigmentary form only, and those who say that it is very rare with the leucodermic. The shield has two sides.

* It gives me the greatest pleasure to bear my testimony to the very high value of the articles contained in this work. It is invaluable to the student of syphilis. I have learnt much from it and hope to learn more. If, however, there be a place of purgatory for bad index makers, I fear that whoever compiled its index will have a long stay. The words "pigmentary syphilis" are indexed, but under them the reader is referred only to an unimportant half-page on the general topic, and no mention is made of an excellent four-page original article by Mr. Arthur Shillitoe, several of which pages bear that heading in large type.

† It may be suspected that, although Mr. Shillitoe has given us a beautiful portrait of syphilitic leucoderma, he is in these statements dealing chiefly with cases which were mainly pigmentary. All his patients were, he informs me, women.

Unfortunately the colours have undergone some change, and it is not so clear as could be wished. Author's diagnosis: Syphilide pigmentaire.

2. A chromo-lithograph from Chotzen's *Atlas*. The neck of a young woman exhibiting in the most definite manner large areas of dull white arranged dapple-wise on a brown skin.

3. From Chotzen's *Atlas* we have one designated "Lues: Leucoderma colli." It shows the back of the neck and shoulders of a dark-haired young woman dappled over with white patches which cover almost the entire surface. The pigmented network is not very dark and by no means conspicuous.

4. In one of Neumann's two portraits the front of the neck and upper part of the bust are shown, and the condition of dapping is very definite. "Leucoderma syphiliticum."

5. Copied from the St. Louis Hospital collection and published in the *Atlas* edited by Dr. Pringle, we have shown the side of the neck of a young woman of a dark, swarthy skin. The skin of the neck is darker than that of the shoulder, and is dappled over with white ill-margined patches about the size of fourpennylbits. In several instances these have become confluent. The ground network is very dark.

6. Mr. Shillibe's portrait represents the side of the neck of a young woman with brown or Auburn hair. It is dappled with white patches, which cover the greater part of the surface.

7. Tafel 157 of Kaposi's *Atlas* represents the back of the neck of a woman with brown hair. Numerous small spots are scattered over the neck, not larger than split peas, and all of them consisting of a white ring, which in some instances encloses a dark centre like the nucleus within a cell. The enclosed nucleus about the same tint as the ground colour. The patches are in some places confluent, and they cover the greater part of the surface. The diagnosis is "Leucoderma syphiliticum. Pigment syphilis." It can scarcely be considered to be either pigmented or leucodermic, but only congested. It resembles the following:

8. Number 210 in the supplement to Jacobi's *Atlas* has the diagnosis "syphilis maculosa congestiva, leucoderma syphiliticum." It represents the front of the bust, shoulder, and neck of a young woman, which is dappled all over with a pink eruption, which encloses lighter coloured spots. On the front of the neck these spots are white. It is tolerably clear that a diffuse erythematous condition has brought out the dappled pattern of the skin. Only on the neck is there evidence of pigmentation.

9. Tafel 158 from the same *Atlas* and with the same nominal diagnosis represents the front of the trunk from the nipples to the upper part of the thigh, marbled or dappled all over by a pigmented network. The contrast in colour is not very great. The neck and shoulders are not shown. A man.

10. A second portrait of Neumann represents the back of the neck and almost the entire trunk. The groundwork of the entire skin is very dark, swarthy rather than black, and it is spotted over with darker patches the arrangement of which it is difficult to interpret. On the back of the neck, however, there occur definite areas of white skin enclosing darker spots, as in Kaposi's portrait mentioned above. Across the loins the condition of mapped-out dapping is definite, and the paler spots have dark centres. The contrast in colour is nowhere very marked.

11. The portrait published by Dr. Taylor of New York. The effect is a marbled one. The patches are very dark, and Taylor distinctly recognizes three forms.

12. A portrait given by Dr. MacLaren's valuable *Atlas of General Diseases* (Plate 12). This was published in 1887, but I have only recently found it.

It will be seen that these portraits present us with some interesting problems. They are not all alike. Two of them show the dappled condition occurring over the whole trunk, and in one of them, perhaps both, the patient was a male. Two of them showed a condition which has possibly hitherto escaped notice in England—I desire to speak with the utmost caution—the presence of a dark nucleus in the centre of the white patch.

Now, if we observe the arrangements of colour on the skins of animals to which I have already adverted, we have at least three distinct types as regards the relation of patches to ground.

In the leopard black patches occur on a yellow ground, and many of the patches have yellow centres.* In a few of the latter black nuclei occur, which are thus surrounded by yellow, which again is margined with black. This is exactly what occurs, but in reverse order, in the portraits of leucoderma syphiliticum given by Neumann and Kaposi respectively.

In the giraffe dark patches are mapped out on a yellow ground. The ground in one variety is so scanty as to be little more than lines, but in another it may increase so as to comprise the greater part of surface and to reduce the patches to comparatively small areas.

Thirdly, we have the pattern shown on a deer or dappled horse, in which light-coloured patches, mostly round and

of very various dimensions, occur on a darker ground. This is the condition usually realized in syphilitic leucoderma. It may be further noted that on some regions (see loins and neck of Neumann's portrait) the pigmented areas are squared rather than round, in exact imitation of what occurs in the giraffe, and in some of the regions of skins of leopards and other animals.

Fournier, who devotes one of his admirable clinical lectures† to "Syphilide Pigmentaire ou Ephelique," is emphatic in declaring that this condition stands apart from other syphilitic conditions, and should be studied by itself: "Accident très bizarre, très curieux, qui s'éloigne de tous égards des autres déterminations cutanées de la vérole." He does not admit that the white "taches" are in any degree decolorized, but regards them as normal skin. He had seen but one case in a male. He thought the condition incurable by specifics and that it never lasted less than one or two years and often longer.

He distinguished it from Addison's disease by stating that in the latter the pigmentation is general and uniform, "non-tachetée." If, however, we deny, with him, that the white patches are other than of normal tint, then this condition is "non-tachetée" also, for it is the pigmentation of the ground which is excessive, and this is not tachetée. Thus we reject altogether such terms as "macular lesion" as inapplicable, and come to the conclusion that the condition is one of diffuse melanoderma plus the peculiarity of a normally pale skin in patches. This brings us very near to the suggestion of a functional temporary and minimized type of Addison's disease, due, possibly, to derangement of the suprarenal capsules. Fournier denies, and I cannot but think with good reason, that it can be regarded as in any way secondary to preceding syphilitic eruptions.

We may, I think, safely assume that the peculiar patterns evolved in cases of this affection are physiological, and due to original organization and not to disease. Building on this assumption, I would further suggest that in secondary syphilis, disordered function of the suprarenal and other organs favours the accumulation of melanin in the cells, and that, finally, exposure to light brings about its deposition in unprotected parts. Thus we explain the preference of the malady for the female sex, and for the neck and bust, and its tendency to persist.

We may conjecture that the affection is far more common in non-syphilitic subjects than has yet been suspected. If some observer, as zealous and keen-sighted as Mr. Shillibe, would conduct a series of control observations on healthy individuals—brunettes by preference, but not excluding those of the male sex—we should probably obtain some very interesting facts. In the meantime I would invite those interested in the matter to pay an observation-visit to the Zoo, and afterwards to devote half an hour to our Chenies Street Museum.

A CASE OF VINCENT'S ANGINA.

By J. T. C. NASH, M.D., D.P.H.,

CORNER MEDICAL OFFICES OF HEALTH FOR NORFOLK.

The following case appears to suggest that the organisms associated with the name of Vincent might after all be merely ordinary oral parasites which happen to find a suitable nidus for multiplication in certain throat conditions, especially where there is a tendency to the formation of a false membrane through the action of streptococci or pneumococci, or even the *Bacillus diphtheriae*: but it is only just to state that a previous case of Vincent's angina had occurred in the same house in an adult female in the preceding August. In this case, also, Vincent's organisms and streptococci were found bacterioscopically.

Mlle. P., aged 20, complained of severe headache on October 16th, 1906. On the 18th she noticed a pricking pain in the throat on the right side, accompanied by some dysphagia. Appetite good, and no constitutional signs of any moment beyond headache, which persisted for some days.

On October 20th, 1906, the patient was examined by me. She was a pale, thin, and delicate-looking young woman, with a fair complexion, and a few freckles on the nose and cheeks. She had a slight fever, and was otherwise well. The throat was examined, and a small, white, circular patch was seen on the right side of the pharynx, about the size of a pea. The patch was slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 21st, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 22nd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 23rd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 24th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 25th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 26th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 27th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 28th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 29th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On October 30th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 1st, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 2nd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 3rd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 4th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 5th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 6th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 7th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 8th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 9th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 10th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 11th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 12th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 13th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 14th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 15th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 16th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 17th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 18th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 19th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 20th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 21st, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 22nd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 23rd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 24th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 25th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 26th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 27th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 28th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 29th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On November 30th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 1st, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 2nd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 3rd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 4th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 5th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 6th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 7th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 8th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 9th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 10th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 11th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 12th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 13th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 14th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 15th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 16th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 17th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 18th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 19th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 20th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 21st, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 22nd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 23rd, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 24th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 25th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 26th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 27th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 28th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 29th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On December 30th, 1906, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 1st, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 2nd, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 3rd, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 4th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 5th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 6th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 7th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 8th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 9th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 10th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 11th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 12th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 13th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 14th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 15th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 16th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no other symptoms.

On January 17th, 1907, the patient was examined again. The white patch had increased in size, and was now about the size of a walnut. It was still slightly raised, and had a yellowish centre. The surrounding mucous membrane was normal. The patient was otherwise well, and had no

Clinical Signs.

On examination the tongue was normal, and there were no enlarged glands; a white membranous patch was visible between the pillars of the right fauces, and there was slight nasal discharge.

Bacteriological Examination.

A swab taken from the white patch of deposit was first rubbed on blood serum for incubation at 37° C., and then on a clean slide for immediate examination. After standing with Loeffler's methylene blue, the immediate examination revealed numerous fusiform bacilli and spirilla, the organisms described by Professor Vincent. These failed to grow on the inoculated serum, which after twenty-four hours' incubation at 37° C. revealed the presence of streptococci.

Treatment.

The treatment adopted was that which is recommended for angine de Vincent—namely, tincture of iodine locally, and potassium chlorate internally.

Result.

The organisms of Vincent disappeared rapidly, the streptococci more slowly, but recovery took place in a week.

The data in this and other cases mentioned are too meagre to permit any reliable conclusion to be drawn, but in each of my cases it seemed probable that street dust inhaled accounted for the sore throat and streptococci, and that Vincent's organisms were merely accidental, but in view of Vincent's own experience and descriptions further study of similar cases is required.

I am strongly of opinion that if more throat swabs were subjected to immediate examination than at present obtains, and Vincent's organisms looked for, it would be found that these organisms are not so rare as is thought.

The question of their pathogenicity also requires further investigation, and appears to be worth the attention of the clinical pathologist.

The point to be decided is this: Is Vincent's angina a sufficiently distinct disorder to deserve a specific designation? The symbiosis of spirilla and fusiform bacilli point in this direction, as also the fact that the particular spirilla are difficult of cultivation. They really seem to be more of the nature of spirochaetes.

The above notes were written nearly two years ago. There appeared in the issue, November, 1908, of the *Journal of the Royal Institute of Public Health* a contribution by Dr. M. A. Arnold on Vincent's organisms which corroborates the views I have expressed. Dr. Arnold's contribution is well worth attention. The clinical appearance of the membrane seen on the fauces in the cases, in which I have examined for and found Vincent's organisms, is very suggestive of diphtheritic membrane. I am afraid my own opportunities of further study of these organisms are now likely to be few, but I venture to hope others will follow the matter up.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

MENDELIAN HEREDITY IN ASTHMA.

As I think the enclosed chart, showing, in black, the members of a family who have been afflicted with

spasmic asthma, will be of interest to Mendelians, I shall be glad if you will publish it.

The numbers—10 normal and 10 abnormal descendants—are in accord with Mendel's theoretical 50 per cent. of each class in such cases, for there was almost certainly a heterozygous abnormal parent of those shown in the first line.

Wrexham.

H. DRINKWATER.

DIPTEROUS LARVAE INFECTION.

It must be an uncommon experience to have two cases of infection by dipterous larvae under one's care at the same time. The method of infection in the one case and the consequence of the infection in the other may warrant their being reported.

CASE I.—Mrs. B., aged 55, an asthmatic, while sitting sewing, felt a fly under her right nostril. She at once tried to expel it by blowing the nose, but without success. An attack of asthma coming on at once, she had recourse to the fumes of a powder which she habitually used at such times. The fly, not quite dead, fell out, but could not be found. This was on a Wednesday afternoon. Severe attacks of sneezing troubled her the same night, and the next morning there was a bloody nasal discharge. The nose began to swell, and the discharge became more bloody and the sneezing more annoying. By Friday she could not leave her bed: by Saturday night the bleeding was sharp and the swelling had spread to the cheeks and eyelids. Such was her condition on my seeing her on Sunday morning. In addition there was a foul, sanious discharge, the lining membrane was much swollen and cracked, the pain and distress severe. The septum nasi showed an old-standing perforation centrally. The nose was washed out with a saturated solution of boric acid and an antiseptic inhalation given. By next day the patient's distress was so serious that Dr. Marry was asked to see her with me. The nose was douched several times a day with potassium permanganate, which kept down the fetid smell, but gave no other relief. By Wednesday morning the discharge of maggots began and kept up for about ten days. A perforation occurred through the right nostril just below the nasal bone. As the right ala became very much swollen and blocked the passage it was incised, and a small nest of maggots was revealed. They spread into the right cheek up to the lower eyelid; they burrowed into the gums and appeared in the mouth. In spite of douches of hydrogen peroxide, mercury perchloride, and permanganate, they kept on appearing up to the number of about a dozen and a half each day. Between 100 and 150 maggots must have been passed in all. They left the nasal cavity disorganized, and bone exposed in many directions. I secured one of the maggots, which were evidently too large for those of the house fly, and put it in a bottle. It hatched out a blue-bottle. The accompanying photograph shows the fly and its case.

CASE II.—While attending the last case I saw an elderly lady who had an epithelial tumour the size of a small hen's egg growing in front of the left ear. It had begun to bleed. On examining its base, which was about 1½ in. by ¾ in., I saw a few maggots. Evidently the bleeding was due to their destruction of the tissue where the vessels entered. In spite of strong applications for their destruction the maggots, which proved far more numerous than I thought, succeeded in riddling the tumour in twenty-four hours, causing pretty severe loss of blood. By next day the tumour was fetid, the bleeding continuous, and the face as far as the eye oedematous. Dr. Marry saw the case with me, and we decided to remove the growth with the cautery. The whole centre was a mass of maggots. When the tumour was removed down to the level of the skin a large nest of maggots was found in the cheek, and had to be destroyed with the cautery. They had evidently developed from ova of the housefly, being much smaller than those of the previous case. Promptly the bleeding stopped and the swelling disappeared, leaving only the scar resulting from the use of the cautery.—I am, etc.,

Trinidad, B.W.I.

STEPHEN M. LAURENCE, M.B., C.M.

OEDEMA OF THE EYELIDS WITH PYREXIA.

My attention has been drawn to an article in your issue of December 12th, 1908, by Dr. Spriggs, under the title of

"An Epidemic of Influenza, Characterized by Oedema of the Eyelids."

As several pyrexial cases in which this phenomenon of oedema of the eyelids was a prominent symptom occurred in this town during the latter half of last year, I am prompted to offer the following remarks. In all some 9 or 10 cases of this description have been brought to my notice, 3 of these occurring in my own practice and 5 in that of my neighbour, Dr. W. F. Lloyd, of Windsor. While the symptoms presented by these cases showed great similarity one to another, they were hardly such as to suggest an influenzal origin to either of us—though, considering the protean character of this malady at the present time and the diversity of opinion as to its real nature, it is of course impossible to assert that our cases could not have owed their origin to this cause.

The cases seen by us approximated more to a gastrointestinal type—some disorder of the bowels, either diarrhoea or constipation with flatulent distension, being present in every instance. In 3 cases in which the fever was unusually prolonged a suspicion of enteric fever was aroused, but when the blood was tested for Widal's reaction the result was negative. The oedema of the lids was in every instance early and transient, disappearing mostly within forty-eight hours. It was, however, a very prominent symptom, sufficient always to attract the attention of the patient and his friends. In no case were the eyelids reddened, nor were the conjunctivae observed to be injected. The pyrexia was mostly greater than in the cases related by Dr. Spriggs. In two of my cases it reached 103° and in the other 102° F. In no case was the patient suddenly prostrated by the attack as so often occurs in influenza. All my cases were walking about in a febrile condition when first observed, and had to be sent to bed. Albuminuria was not present in any case. The duration of the fever varied; the shortest period of illness observed was ten days and the longest three weeks. No heart or lung symptoms were noticed, and the fancies were invariably healthy; in fact, in no case was any cause discovered sufficient to give rise to the pyrexia. Notwithstanding this these patients were decidedly ill, apparently more so than the cases already related in your columns, for in one or two instances, notably one case of Dr. Lloyd's which lasted three weeks, the condition was such as to give rise to a certain amount of anxiety.

We have thought it well to place a brief record of these cases before your readers, not with the idea of contrasting them with the cases related by Dr. Spriggs, but in the hope that others who may have met with this somewhat unusual symptom in conjunction with a pyrexial condition may be induced to relate their experiences, and so possibly be the means of enabling us to classify similar cases that may confront us in the future.

CHAS. R. ELGOOD.

INAUGURAL SYMPTOMS (GASTRIC ULCER).

I READ Mr. Moynihan's address with very great interest, but I scarcely anticipated that I should have such an early opportunity of putting his advice to practical use or of verifying his statements as to the inaugural symptoms of ruptured gastric ulcer. His address was published on November 28th, and on the following day, about 5.20 p.m., I received a very urgent summons to see a young woman who lives only a few doors from my house. I returned with the messenger, and the history given me was that about seven or eight minutes previous to my arrival, as she was lying on the couch, she was seized with a sudden overwhelming pain in the region of the stomach, and felt sick and faint. She is said to have lost herself once or twice owing to the intensity of the pain, and to have become very pale.

I found her in a reclining posture on a couch, her expression extremely anxious, eyes turned up, lips bloodless, and with beads of perspiration on the brow. The skin of the face, chest, and abdomen was very pale. Her arms and hands (which were exposed, as she was wearing a short-sleeved blouse) were warm, as also were her legs and feet. She made one or two attempts to vomit, but only brought up a teaspoonful or two of glairy-looking fluid. Her pulse on my arrival was 86, regular and about normal in strength and volume, but after the attempts at vomiting it became 96, and remained so until I left her. Her respiration was 34, short, shallow, and moaning on expira-

tion. The temperature in the axilla was 98.6°. There was great tenderness over the region of the stomach about 2 in. below and to the inner side of the left costal margin. The abdominal muscles were very rigid, but it was noted that those of the left side were much more so than those on the right. There was no distension of the abdomen. The patient was a young woman aged 23 years, and I had treated her two years ago for an attack of hæmatemesis.

From the above symptoms I diagnosed that she had a ruptured gastric ulcer, and I recommended her immediate removal to the Leeds General Infirmary. This was done, and Mr. Moynihan operated as soon as she arrived, finding a perforation of an ulcer on the lesser curvature of the stomach, near the cardiac orifice.

I think this case may be of interest, coming immediately after the publication of Mr. Moynihan's address, and verifying in such a striking manner his description of the inaugural symptoms of this condition, as opposed to the usual textbook descriptions. I am doubtful also whether any case has been observed so early, and on that account may be thought worthy of record.

Leeds.

JOHN EXLEY, M.R.C.S. Eng., L.R.C.P.I.

IONIZATION IN CHRONIC ENDOMETRITIS.

DR. HERMAN's instructive paper on the "Use and Abuse of the Curette," in the JOURNAL of December 5th, 1908, encourages me to advocate a method suggested by Dr. Samuel Sloan, of Glasgow, and others for the treatment of chronic endometritis by means of ionization. The details of the technique are of the simplest character, and can be carried out by any physician.

The vagina having been previously douched with an antiseptic solution, a sterilized copper sound, varying in calibre according to need and having an insulated stem connected with the positive pole of the continuous current of an electric battery, is introduced into the cavity of the uterus. A large pad of absorbent cotton or of several layers of lint 6 in. by 6 in., soaked in a saline solution, is laid on the hypogastrium and connected with the negative pole. The circuit is then closed and the current gradually increased until a record of 20 to 40 milliamperes is reached, and this maximum is maintained for about fifteen minutes; afterwards the current is gradually reduced to zero, then the commutator is changed and 5 milliamperes of a reverse current is allowed to pass for three to four minutes in order to loosen the copper sound, which otherwise will be found to be tightly grasped by the neck of the uterus. The current is now again reduced to zero and the sound gently withdrawn. By this means the internal surface of the uterus is thoroughly cauterized. As there is abundant discharge for a day or two after the operation, vaginal douching is recommended.

The advantages of this method are that the endometrium, while thoroughly dealt with, is not wounded, any abraded surface is encouraged to heal, there is no danger of sepsis or of septic absorption, the discomfort to the patient is but slight, no anaesthetic is required, and the patient does not need to retire to bed after the operation.

In order to observe how the copper is carried into the tissue of the uterus, let the physician take a piece of raw beef and plunge a thick copper wire connected with the positive pole into one side, while a platinum electrode in connexion with the negative pole is introduced into another part of the beef at a distance of 5 to 6 inches. In a few minutes after the current has been turned on, the positive copper electrode will be found tightly fixed in the beef, while the negative platinum electrode will be only loosely held, and a streak of the green oxychloride of copper will be noticed starting from the copper electrode and diffusing gradually through the mass of beef towards the negative pole.

I have employed this method with gratifying results in several cases of endometritis accompanied by chronic discharge during the menstrual periods, and also in cases of menorrhagia, both with or without pain. The discharge is lessened or made to disappear and the amount of menorrhagia is reduced. I am convinced that this plan of treatment deserves an extended trial and all the more that it offers in many instances an effective substitute for the process of curettage.

Reports

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF THE BRITISH EMPIRE.

THE ROYAL BOSCOMBE AND WEST HANTS HOSPITAL.

CASE OF SUPPURATING DERMOID OF MEDIASTINUM.

(Reported by THOS. B. MOUNT, M.B., CH.B., House-Surgeon.)

A boy, aged 17, was admitted under the care of Dr. Bottomley on October 7th, 1908, with the following history:

History and Clinical Course.

He had had good health up to November, 1907; he was then laid up with chilblains and blisters of the toes, which persisted for some weeks. Cough commenced in January, and swelling of the abdomen, followed by oedema of the legs, was noticed in April, 1908.

On admission he was suffering from general oedema and ascites; both increased rapidly in spite of medical treatment and repeated tapping, and the patient died on November 25th. The physical signs were: Dullness on percussion behind and for about an inch on either side of the manubrium sterni continuous below with an enlarged cardiac dullness. Over this area the breath sounds were tubular without accompaniments, and vocal resonance increased. There were no cardiac murmurs. The urine was of about normal amount, and contained no albumen till a few days before death. The evening temperature was usually between 100° and 101°. The diagnosis of tuberculous glands in the mediastinum obstructing the superior and inferior venae cavae was made.

Necropsy.

On opening the thorax, the pericardial sac appeared to be very much enlarged, but this on incision proved to be a large cyst, distended with purulent fluid, which contained yellow fatty masses and long hairs. The cyst was adherent to the diaphragm below; above, a narrow neck ran up in front of the superior vena cava, and communicated with a large loculus which lay anterior to the arch of the aorta and its branches; its wall was lined with scaly, fat-covered integument, and the cavity was at one point constricted by a broad fleshy band. The heart lay embedded in the thick posterior wall; no sign of any pericardial sac could be found, and the cyst appeared either to have grown from the pericardium, or in its growth to have become very completely adherent to it. The chambers of the heart, especially the auricles, were flattened, but otherwise healthy. The pleural sacs were obliterated by extensive adhesions between the layers, and the lungs, liver, and other viscera were congested, but except for this showed no disease.

Streptococci were grown on culture from the cyst fluid.

IN an investigation of the solubility of lime in water, an account of which was presented to the Chemical Society recently, Messrs. G. T. Moody and L. T. Leyson have endeavoured to avoid the errors which largely vitiated the results obtained by earlier workers, and some of the results obtained in the course of the research are of more general interest. Lime prepared from chalk consistently showed an apparently greater solubility than pure lime from calcite, and this was found to be due to the presence of impurity, chiefly silica, which is not revealed by the ordinary test of judging the strength of lime water from its alkalinity. As is well known, the solubility of lime is less at higher than at lower temperatures; but the authors of the paper found that when the temperature of saturated lime water was raised it remained supersaturated, and only gave up the excess with extreme slowness; on the other hand, solutions of lime were appreciably weakened by passing through filter paper or other fibrous substances. The official lime water is intended to be a saturated solution of lime at ordinary temperatures: the deficiencies in strength which are occasionally found in the article supplied in shops are usually due to careless preparation or to exposure to the air, but it appears that other considerations must not be entirely ignored.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

BIRMINGHAM BRANCH.

PATHOLOGICAL AND CLINICAL SECTION.

Birmingham, Friday, November 27th, 1908.

Professor LEITH in the Chair.

Rhinitis Caseosa.—Professor LEITH and Dr. C. J. LEWIS gave an exhibit of bacterial cultures obtained from a case of rhinitis caseosa. The clinical history of the case, communicated by Dr. Glegg, was as follows: The patient, a woman of about 40 years of age, was sent to Dr. Glegg by an ophthalmic surgeon, who suspected an intranasal cause for the lachrymal obstruction from which she was suffering on the right side. Two years ago she had influenza, and since then the right side of the nose had become stopped up. She also had several carious teeth removed from the upper jaw on the right side. There had been a good deal of frontal pain on that side. The right side of the nose was filled with a mass of putty-like material, with an intensely fetid odour. This was removed under an anaesthetic, and the right maxillary antrum opened by removing a portion of its anterior wall. The mucosa was hypertrophied and polypoid. The small polypi were removed with cutting forceps, but the mucosa was not curetted. A large opening was found in the outer antral wall. This opening was enlarged below, and the cavity packed with gauze from the nasal cavity into the antrum. The gauze was removed next day, and alkaline lotion used thereafter. The discharge has entirely ceased, and the nasal cavity is clear. Now, three months since the operation, there was no recurrence of the former symptoms. On examining the material removed by Dr. Glegg, Professor Leith and Dr. Lewis found several organisms, which they deemed to be non-pathogenic, and also a streptothrix, which they consider to be probably pathogenic. The characters of the suspected streptothrix are:

1. Microscopically—is a typical streptothrix, Gram-positive, and not acid fast.
2. Cultures. (1) Agar—Colourless growth invading medium, becomes covered on surface with white chalky bloom, gradually assuming a pinkish tint. (2) Stab-jelly—slowly liquefied formation of a bubble. (3) Broth—forms pellicle, and forms flocculent deposit at bottom. (4) Milk—forms pinkish film adherent to tube. (5) Serum—similar to that on agar. (6) Potato—A colourless growth which speedily forms the chalky bloom. This bloom is much more chalky than that of *Streptothrix nigra*.
3. Pathogenicity—doubtful. Tested thrice since isolation. First animal (guinea-pig) died in three days, and a different germ obtained from its tissues. Second animal (guinea-pig) died in three days, and no germ recovered from its tissues. Third animal (rabbit), inoculated on November 23rd, 1908, is still alive and well.

Tubal Pregnancy.—Mr. J. FURNEAUX JORDAN reported four cases: (1) Aged 29. Seven children, youngest aged 3. Losing for nine weeks before operation on September 25th, 1908. It began as an ordinary menstrual period, and was free from any accompanying pain until the last few days. There was acute tenderness and a distinct swelling in the left half of Douglas's pouch. The tube was dilated, and protruding through the dilated fimbriated extremity was an organized blood clot. A quantity of dark blood and blood clot occupied the pelvis. Sections taken across the tube showed that only a limited portion of the wall of the tube had been stretched by and formed a covering to the tubal mole. At first sight it appeared that the mole was intramural, but a careful examination revealed a thin, flattened-out layer of tubal mucous membrane lining the entire covering. It is possible that this epithelial lining was pushed in front of the pregnancy as it made its way into the tube wall. Several chorionic villi were found in the clot. (2) Aged 31. Married eighteen months; one child,

9 months old. Seven months ago was infected with gonorrhoea, from which she said she had quite recovered. The menstrual period, due on September 2nd, did not come on until September 9th, and from then until October 16th, when first seen, the loss had been continuous. Very little pain, except on September 9th, the day of onset, when it was severe in the lower part of the abdomen. There was a large tender swelling filling up the left half of Douglas's pouch. On October 25th the specimen shown was removed. It consists of the left appendages, and the outer end of the tube is dilated and occluded by adhesions to the ovary. Its contents were thick blood, fluid, not clotted. In the left ovary was a cyst the size of a small apple. In the middle of the tube, proximal to the dilated portion and distant $\frac{1}{2}$ in. from it, was a small swelling. Microscopically this proved to contain a small, firm clot with chorionic villi in it. It occupied the lumen of the tube, the wall of which showed no sign of thinning in any portion. (3) Aged 41. Married seventeen years; five children, youngest aged 6. One miscarriage two years ago, ever since which she has had pain in the left side. For two months has had continuous uterine haemorrhage, varying in quantity. It began as an ordinary period. The pain has been very severe in the lower left part of the abdomen. A small swelling could be detected in the place of the left tube. At the operation on October 5th an unruptured left tubal pregnancy was removed. The site was the middle third of the tube, and in its thickest part the swelling was nearly $\frac{1}{2}$ in. in diameter. Microscopic slides show a small organized blood clot occupying the lumen of the tube, surrounded everywhere by the folds of the tubal mucous membrane. In the clot are chorionic villi. There is no sign of any invasion of the tube wall by the pregnancy. (4) Aged 28. Married one year. In January, 1905, went two weeks over her time, then lost for a week, stopped for three days, lost again for a fortnight, at the end of which time she was seen with Dr. Sturge. Pain was not marked. Douglas's pouch was completely occupied by a firm, tender swelling, which was diagnosed as a peritubal haematocle. At the operation, on February 20th, the swelling proved to be a right ovarian cyst, about the size of an orange. In the very middle of the tube of the same side was a very small swelling, which Mr. Furneaux Jordan cut open. There was immediately extruded a small clot. Microscopically it proved to be a tubal pregnancy. Slides and photographs of slides were shown, in which the relations of the parts were clearly seen. A chorionic villus with Langhans's cells and syncytial cells, and also, adjacent to the tubal mucous membrane and in the muscular wall of the tube, a number of decidual cells. The microscopic slides of Cases I, II, and III were very kindly cut by Dr. Mackie, pathologist to the Birmingham Hospital for Women. Those of Case IV were cut by Professor Leith, of the Pathological Department of the University. To Professor Leith the author expressed his indebtedness for his interest in the case, and for the beautiful and excellent photographs he took for him.

Perforation of Small Intestine.—Dr. MACKEY showed organs from a case of ulceration and perforation of the small intestine associated with chronic interstitial nephritis. The patient, a woman of 27, had been admitted into Queen's Hospital on account of profuse haemorrhage from the bowel; she had neither pain, tenderness, nor rigidity, and the haemorrhage soon became very slight. There was no diarrhoea; the temperature remained normal. On the eighth day after admission she suddenly developed all the signs of general peritonitis, and died. At the autopsy the lower half of the small intestine was infiltrated with blood; the mucous membrane was the seat of numerous—over a hundred—small ulcers, three of which had perforated and caused a general peritonitis. The mesenteric vessels appeared normal; the heart showed marked hypertrophy and the kidneys well-marked interstitial nephritis. Dr. Mackie thought that there had been a severe haemorrhage into the wall of the bowel, and that the ulceration of the damaged mucous membrane was secondary.

Malformation of Internal Female Genitals.—Mr. H. P. COLE showed a specimen which consisted of a mass representing the entire internal genitalia removed by operation from an unmarried woman, aged 22. The operator was Mr.

Jordan Lloyd, who kindly gave permission to demonstrate the case, and provided the clinical history. The mass removed lay on the pelvic floor, slightly to the left of the middle line, between bladder in front and rectum behind. There were no broad ligaments, no round ligaments, and no ovaries. The mass was rounded in outline, shaped somewhat like a uterus, and measured $\frac{1}{2}$ cm. long by $2\frac{1}{2}$ cm. broad. No lumen was present. The cut surface showed the presence of numerous small whitish encapsuled areas, enclosed by a definite cortex. On either side were two folds connected to the central mass, above and below, but separate from it between these points. In the free edge of this fold was a distinct unbroken tube with muscular walls and a lining layer of large cubical cells. Further investigation was needed definitely to determine the nature and origin of these structures, but it was suggested that the central mass might represent the uterus filled with an adenomatous growth of the developing mucous membrane, or that the mass was really an instance of the inclusion of one organ, or a part of one, within another; in other words, an embryonic "rest." The tube in the lateral fold was regarded as a remnant of the Wolffian duct, or possibly of the Mullerian duct.

Lymphatic Leukaemia.—Dr. DOUGLAS STANLEY showed the spleen and stomach from a case of lymphatic leukaemia. The patient was a woman aged 81, and was shown as a living case at the March meeting, 1908. The cause of death was exhaustion, due to a gastro-colic fistula.

E. HASTINGS TWEEDY, M.D., President, in the Chair.

Intermenstrual Pain.

DR. R. D. PUREFOY, in a paper on intermenstrual pain, said that one of the least common and least understood varieties of pain connected with and dependent on menstruation was that to which Priestley in 1872 applied the term "intermenstrual." Medical literature furnished but scanty records of such cases, and details as to treatment and its results had been seldom supplied. It often proved rebellious to treatment, and showed marked liability to recurrence. It was generally met with between the ages of 25 and 35, and was commonest in sterile women or those who had not been recently pregnant. Some writers had described the pain as paroxysmal and sudden in occurrence and severe in degree; and many attributed it to the condition known as hydrosalpinx. The speaker was unable to agree with those statements as to the nature of the pain and its causation. In the most typical cases there was but little discoverable disease of the uterus and appendages, and in only a few cases was it associated with such watery discharge as might be attributed to leakage from a hydrosalpinx. Treatment should be constitutional to improve the general health, and local if disease of the uterus or appendages could be detected. A second paper on the same subject was read on behalf of Dr. SPENCER SHELL. In the discussion which followed, Dr. WILSON said he thought that where there were local lesions which could be corrected, with the result that the pain ceased, the case hardly came under the head of intermenstrual pain; neither did cases in which congestion of the ovaries was relieved by the loss of blood at the period. The difficulty of treating cases of pain that came on a definite number of days after a menstrual period, and ceased a definite number of days before a period, was very great, and although the drugs mentioned by Dr. Shell might give relief, it was a matter of considerable doubt as to what the condition really was. Dr. ASKE thought the condition was probably due to some form of toxæmia arising from an excess of internal secretion of the ovary. Dr. NEILL said that salicylate of menthol had recently been advised for relief of pain. Dr. FITZGERBON said that in speaking of intermenstrual pain there was a tendency to mix up a variety of different diseases. They should keep in mind that the pain should be one which occurred at a fixed time between the periods, and in which there

was no definite organic disease. The ignorance which existed as to ovulation made it difficult to say certainly that it was congestion of the ovary that caused the pain, but he expected that Dr. Sheill's suggestion of circulatory treatment would improve the condition. Dr. KATHERINE MACKENZIE said she did not find the condition common in an excessive degree. She found aspirin rather a dangerous drug, as far as its gastric symptoms were concerned, although it certainly relieved pain. She found phenacetin to do good, if ammonium or antihistaminics were given, they should be given after food and with tea or coffee, which neutralized their effects. She regarded both drugs as dangerous, because they were compounds of antifebrin. The President said that women suffered from constipation and congestion of the pelvic organs, and he believed that this congestion would be relieved by free purging better than by the drugs mentioned. He thought that in most cases not due to constipation or neurasthenia they would find some disease of the tubes which might give no evidence of their condition to the examining finger. Dr. PEARSON, in reply, said he agreed with Dr. Fitz-Gibbon's limitation of cases, but such typical cases were rare. He was very sparing in his prescription of drugs, and considered that anything like repeated use of the coal-tar remedies was greatly to be deprecated.

LIVERPOOL MEDICAL INSTITUTION.—At a meeting on December 17th, 1903, Mr. R. KELLY read a note on the *Treatment of general peritonitis by the Murphy method*. After giving an account of the axioms laid down by Murphy in this condition, namely, early and speedy operation, removal of offending appendix, or closure of bowel wound, the Fowler position and proctocolysis, he demonstrated an apparatus to effect the continuous rectal irrigation, and illustrated his remarks by five cases. Mr. W. THELWALL THOMAS had been much impressed a few years ago by Murphy's demonstration of the advantages of the Fowler position and continuous rectal perfusion, and resorted to it in all cases of septic peritonitis with marked success. Mr. LITTLETON JONES read a note on a case of *Aneurysm of the femoral vein*. The history was that, after violent exertion in lifting a sail, the man experienced sudden great pain in the groin, which was found to contain a swelling. It was irreducible, and evidently contained fluid, and was thought to be a hernial sac containing fluid. Operation revealed a sacculated aneurysm of the femoral vein, and any attempt to empty it caused constriction of the neck of the sac. The vein was ligated above and below, and the aneurysm dissected out. It was seen to be of recent origin. The man soon recovered, and without any oedema after ligation of so important a vein. In another case the aneurysm was fusiform, and operation was again followed by recovery. These two cases led one to believe that violent exertion might cause rupture of one or more coats of a vein, apart from any predisposition to varicosity, and in that way these conditions might be brought forward as accidents under the Compensation Acts. Dr. A. ALSTON THOMPSON read a paper on *Mechanical and manual massage*, and compared the physiological effects of the two processes. He related his experience with mechanical massage in eye diseases, chronic deafness, chronic abdominal affections, gout, rheumatism and allied conditions, venous congestions, exudations, nervous affections, and gynaecological conditions, and gave a demonstration of his technique.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—At a meeting in December Mr. H. W. W. GRAY read a paper on Bier's method of producing *Local anaesthesia* as applied to a case of amputation at the wrist. It consisted in putting a Martin's bandage round the upper arm, selecting a vein near the bend of the elbow, isolating it, opening it and injecting into it 30 to 40 c.c. of a 1 to 2 per cent. novocain solution. In a few moments anaesthesia was completed, and the amputation was carried out; all that the patient complained of, apart from the discomfort of the tourniquet, was a slight burning sensation at the wrist, and she made an attempt to withdraw the arm while the operation proceeded. It thought necessary a considerable amount of the anaesthetic could be expressed by massage from the open vein after the operation. He commended the method on account of its simplicity and its efficacy and its advantage to isolated practitioners. In another paper Mr. Gray

dealt with *The treatment of burns* by the thorough antiseptic cleansing of the affected area and surrounding parts under anaesthesia if necessary, and thereafter dusting over these areas very freely a powder composed of equal parts of pure boric acid and pure carbonate of bismuth (the subnitrate of bismuth should not be used as it causes intense smarting pain). This powder formed with the early exudate a "seal" which protected the affected area from fresh infection; no gauze, cotton-wool, or bandages should be applied. Any discharge which later might trickle from underneath the seal was wiped away and fresh powder dusted on. He also dealt fully with the treatment of cases sent to hospital after sloughing had started in the affected areas. If sloughs were very adherent, boric acid fomentations, antiseptic baths, peroxide of hydrogen, etc., were used to loosen them and lessen septic absorption. When the slough was loosened, an anaesthetic was given, and the area treated as above. If the parts were not sufficiently disinfected the scab which first formed might swell rather badly; in this case it should be removed in a few days, and fresh boric acid and bismuth dusted on. He had not required to remove a seal on account of decomposition on a second occasion. The parts affected should be kept at rest, but joints should be moved once every morning and every evening to prevent ankylosis. The method did away with the pain of frequent dressings, and resulted in a pliable scar, vascular in constitution, and with no tendency to contract. Dr. MACKENZIE BOOTH, in a paper on anaesthesia in *Intranasal manipulation*, gave his experience of various local anaesthetics with and without the addition of adrenalin. He thought eudrenine and codrenine were best for general use, and gave in detail the various methods of application, and their use in the examination of the nasal cavity. He then described what he considered the limitations of local anaesthesia in nasal surgery, and compared it as a whole with general anaesthesia.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At a meeting on December 17th, 1903, Mr. P. E. BARRETT, President, in the chair, Mr. SIDNEY SNELL showed a little boy from whom he had removed a retrobulbar tumour by Kronlein's operation. The result was very satisfactory, the eye was retained, and the proptosis was gradually diminishing. He also read notes on a case of *Acute bromism* after three 5-grain doses of bromide. There was a bulous eruption on the ears, a tingling sensation in the hands, and coryza. All the symptoms cleared up when the bromide was withheld. Mr. GARRICK WILSON read notes on a case of supposed rheumatic peritonitis. A boy who had suffered from rheumatic fever had acute abdominal symptoms, and was submitted to operation, when there was found a great deal of clear serous fluid. No primary focus could be found. The boy recovered, but convalescence was interrupted by symptoms of acute rheumatism, which were alleviated by salicylates. Dr. ARTHUR HALL showed 2 cases in which remarkable improvement of *Spherocytic leukaemia* followed the use of the x rays. In both cases the patient had been able to work for several months. No bad symptoms had resulted. The red corpuscles had increased with the decrease in the whites. He also showed a case of myoclonus in a man following influenza. The spasms were limited to the left deltoid, trapezius and coraco-brachialis. At times they were very painful. They could be brought on by raising the arm above the horizontal. Dr. F. H. WADBY, in a paper on *Decimal dispensing*, uttered a strong protest against the action of the Board of Trade in establishing a standard metre, kilogram, and litre, differing slightly from the original standards, and differing in such a manner that the British litre, instead of measuring 1,000 British c.c., actually measured 1,000.16 c.c. This defect subverted for calculation purposes that fundamental principle of decimal proportion which was the most valuable characteristic of the real metric system. He deplored the fact that the General Medical Council had introduced these now legalized standards into the *British Pharmacopoeia* of 1893, in place of the original standards which had hitherto been adopted. He also mentioned the suggestion of Professor Parker that our existing national systems of weights and measures admit of convenient correlation of a physical basis in virtue of the circumstance that a cubic inch of water at 122° F. (= 50° C.) weighed exactly 250 grains.

In conclusion, the author urged that it was not reasonable to attempt to establish artificial relations between systems of weight and measure in defiance of those relationships which experience or custom demanded. The dozen was far superior for subdivisive purposes to the ten, and the best solution of all difficulties would be to learn to count in dozens instead of in tens.

PATHOLOGICAL SOCIETY OF MANCHESTER.—At a meeting on December 9th, 1903, Dr. MILLIGAN (President) in the chair, Mr. C. ROBERTS and Dr. C. POWELL WHITE showed two specimens of congenital tumour of the kidney removed by operation; and some similar tumours from the Pathological Museum of the University of Manchester. All the tumours contained cells resembling sarcoma cells, epithelial tubes, muscle fibres, etc. They were distinguished from sarcomata by the presence of the epithelial tubes, which were formed by differentiation from the sarcoma-like cells, and hence these and similar growths had been placed by Dr. Powell White in a class by themselves under the name of "kistocytomata." Sir WILLIAM SINCLAIR gave a short address on peritonitic adhesions, drawing his illustrations almost entirely from obstetrics and gynaecology. He maintained that if the peritoneum was wounded or became inflamed, as, for example, in the slighter attacks of lymphatic infection in childhood, adhesions were inevitable; exceptions must be extremely rare, and could depend only upon the movements of the intestines when the omentum did not come within range. He traced the formation of adhesions from the fibrous exudation stage to the stage of firm, non-vascular fibrous adhesions which displace organs or interfere with their functions. In gynaecology, when adhesions of the uterus could be diagnosed or reasonably suspected, manipulative treatment was futile. Operation was indicated, and details depended upon what was then made out by touch and sight. Inasmuch as adhesions were inevitable, their production in certain operations should be aimed at; they should be made useful and conservative; their formation should not be left to blind chance so that they may become a cause of discomfort or danger. Professor DELÉNE, in a paper on methods of examination of milk, showed that milkborne infections were either direct zoonous infections (for example, tuberculosis), indirect anthroponous (for example, typhoid), or belonged to a mixed class in which the infection was brought about by indirect faecal pollutions (for example, summer diarrhoea). In zoonous infections the pathological state of this fluid might be indicated more or less clearly by alterations in composition, by an excess in the amount of cells, or by the presence of specific pathogenic bacteria. In anthroponous infections there was usually evidence of contamination with extraneous products and of the presence of specific pathogenic bacteria. These, as well as cells and other products derived from the udder, could be separated by centrifugization, and obtained in a thick viscid mass generally known as "skime." Physico-chemical analysis and simple microscopical examination, estimation of the number of "leucocytes," and estimation of the number of bacteria yielded results which had no constant relation to the fitness of the milk and could not be relied upon as bases for preventive administrative action; while determination of the presence of specific pathogenic bacteria by various methods, and of the pathogenic action of milk by inoculation, though very useful in special cases, were too slow for administrative purposes. Measurement of the slime was the only method capable of being used in routine administrative work, but it could not be relied upon to exclude all infectious milk from the market. By this method it would, however, be possible to eliminate from the milk supply a very considerable portion of the unsound milk.

CLINICAL SOCIETY OF MANCHESTER.—At a meeting on December 15th, 1903, the President, Dr. J. J. Cox, delivered an address, entitled *A Due Conservatism in Medical Therapeutics*. In the course of it he deprecated the indiscriminate use of the catheter, both in the case of post-nasal adenoids and for uterine conditions. He referred to the impossibility of keeping pace with the numerous products of the chemist, and maintained that a wise policy held fast to that which had been proven. Stress was laid

upon the value of such therapeutic measures as massage, hydrotherapy, and phlebotomy, which did not always receive the attention they deserved at the hands of the profession. A practical point upon which he felt strongly was the great advisability in infantile ailments of ensuring sufficient sleep, and to this end Dover's powder provided a well-tried and useful means.

CHELSEA CLINICAL SOCIETY.—At a clinical meeting on December 15th, 1903, Dr. A. F. PERCY, President, in the chair, the following were among the cases shown:—Mr. J. HOWELL EVANS: Case of *Tumour of the lower jaw* on the right side about the size of a duck's egg. It commenced two years ago after an alleged injury. It appeared to be lobulated, but there was no positive evidence of cancer. The x-rays showed that the jaw was affected only on the outer side but were negative as regards diagnosis. Dr. ALFRED EDWARDS: A case of *Impetigo erythematosa*, affecting the scalp, ears, backs of hands and fingers, forearms, points of elbows, and hard palate. The scars on the face were pitted, and all the lesions on the limbs were of a "folliclic" character. The exhibitor believed "folliclic" to be merely a nodular form of lupus erythematosis, or ulerythema, and considered that this case confirmed his opinion. Dr. GREY: Three cases of rodent ulcer, 2 healed by the x-rays and 1 by the x-rays and Finson-rays combined. Dr. GUNNING: A case of congested fold of mucous membrane between the first lower bicuspid of each side and the upper lip, in a boy aged 15; also 3 cases to demonstrate the practicability of developing the "fusion centre" of children affected with strabismus, by means of an ordinary stereoscope and "Kroll's pictures." Dr. ASHLEY BALDWIN: (1) An unusual case of *Spina bifida* in a boy aged 6. There was no tumour, but a depressed area over the sixth and seventh dorsal vertebrae, the laminae being present. There was incontinence of urine, weakness of sphincter ani and of the legs, and a tendency to fall down. (2) A case of carcinoma high up in the rectum successfully treated by a double operation, abdominal incision, and subsequent removal of the tumour after forcing it through the anus.

Reviews.
The third volume of KERN'S *"Surgery"* tempts a reviewer to employ exaggerated terms of commendation. The editor deserves congratulation on his selection of authors, and the series of admirable articles which compose this volume forms a high testimonial to his judgement. Dr. Cushing writes first on the surgery of the head, and the chapter is worthy of one who has made many valuable contributions to this subject. He is at his best in his descriptions of cranial injuries and their effects on the brain, a subject by no means always lucidly treated in textbooks. Newer procedures such as the relief of compression in basal fractures and the treatment of injuries of the head in the newborn receive adequate consideration. Operative methods are very fully described and illustrated. The illustrations are also a great feature of the second chapter, by Dr. E. W. Andrews, on the surgery of the neck. Dr. Albert Kocher writes on diseases of the thyroid gland. With the experience of these affections afforded by the surgical clinic of Bern, it is little wonder that the article is a complete monograph of much value. More particularly of interest is the discussion of the group of affections included under the heading "thyrotoxicosis," and of their relations to fully developed Graves's disease. Professor Theodore Kocher's results in 200 cases of Graves's disease are quoted, a mortality of 4.5 per cent. and 65 per cent. of cures.

This article on the nose and its accessory sinuses is by Dr. Harman Smith. It is chiefly notable for its discussion of the modern methods of treating sinus suppuration. Dr. G. E. Brewer writes the two articles which follow, on the surgery of the larynx and trachea and the surgery of the thorax, and again methods of treatment from the chief feature of the text and are abundantly illustrated. In Dr. Finney's article on the breast there are some matters that call for remark. It may be questioned

whether any good purpose is served by distinguishing a new type of "intraocular myxoma" from the fibroadenoma, and as their "characteristic feature" is the projection into dilated epithelial-lined ducts and spaces of papillomatous growths, the relation of these tumours to the cysts with intracystic papillomatous growths, which are described later, requires definition. These matters are mentioned here to call attention to the confusion which still exists concerning the classification of various mammary affections. The necessity for revision is shown by the statement on p. 582 that 50 per cent. of cysts with intracystic papillomatous growths become carcinomatous, which may be paralleled with a statement in a well-known handbook of morbid anatomy that these growths are always benign! Mr. Edmund Owen writes the chapter on the surgery of the mouth, teeth, and jaws. He advocates the Brophy operation for cleft palate, operates on the cleft palate before the harelip, and considers that the most favourable time for the operation is between the ages of 2 weeks and 3 months. The surgery of the tongue is separately dealt with by Dr. Da Costa. For clearing out the glands of the neck he recommends the operation of Crile and others—that is to say, the excision of the whole gland mass in one piece from below upwards, including the internal jugular vein.

The remainder of the volume is devoted to abdominal surgery. The introductory articles are by Dr. J. C. Munro; then follow the surgery of the stomach by Mayo Robson, the surgery of the liver and bile ducts by W. J. and C. H. Mayo, and the surgery of the pancreas and spleen by B. G. A. Moynihan. The mention of these names is sufficient to show the quality of the articles, embodying as they do the views and practice of acknowledged authorities.

OPHTHALMOLOGY.

Owing to an accidental oversight we have not hitherto called attention to a very instructive book on *Preventable Blindness* written by Mr. N. BISHOP HARMAN, whose large experience as Oculist (with care of blind children) to the London County Council schools particularly fits him to set forth his experience in book form. It amounts, of course, to a dissertation on ophthalmia neonatorum, which, although known to all practitioners, is not even yet recognized as being the cause of so much blindness as it really is. It is a disease which can practically always be prevented, and if taken in time can in nearly every case be cured, and yet more than one-third of the blindness among school children is still due to it. If it were included among those diseases which it is compulsory to notify, it is probable that its disastrous effects would almost entirely disappear. Short of that, all that can be done is to educate the public, and particularly all nurses, so that it shall be at once recognized and appropriate treatment adopted. In the book before us a very valuable historical summary of the disease is given. In a short chapter dealing with the causes of blindness it is shown that in the census returns for 1901 there were living between 1,000 and 2,000 persons whose blindness might have been prevented, while in a large series of cases the author found that 36.36 per cent. of the cases in the blind schools were there on account of the ravages of this disease. This total, large as it is, is really less than the true figure, for it does not include cases in which a little sight has been obtained from operations and other means which enables the sufferer to be classified among the partially blind; if these were included the total would exceed 40 per cent. The incidental and clinical character of the disease and the risk of permanent injury are discussed, and an important section is devoted to its contagiousness. This is a point on which the Local Government Board requires instructing, for in answer to a question by Lord Robert Cecil in the House of Commons, Mr. John Burns, the President of that Board, stated that "the danger scarcely existed." That, of course, is absurd, and Mr. Harman well cites as an example to the contrary an instance in which a mother and four children all became infected from one case. A good photomicrograph illustrates the chapter on bacteriology, and then follows one on treatment and another on prophylaxis.

Textbooks on ophthalmic surgery still appear, though whether the supply exceeds the demand is, perhaps, better known to the authors and publishers than to any one else. A book on *Diseases of the Eye* has just been brought out in the series of Oxford Medical Publications, and the author is Mr. M. STEPHEN MAYOU.³ The first chapter, devoted to a description of the methods of examination of the eye, is sketchy; it seems to assume that the reader knows all about the subject, and it is to be doubted whether the beginner could learn much from the meagre details given. In discussing Snellen's test types on page 56, we are told that the types "are graduated, so that the letters at the distance marked over each line subtend an angle of 5' on the retina (the distance between two cones)." If the cones were separated by the space represented by this angle, there would only be room for a dozen or so in the eyeball. As a matter of fact, there is no difficulty in distinguishing things which subtend an angle of one minute or even less, and the letter which Snellen indicates by 5 subtends at 6 metres an angle of five minutes, with an angle of one minute subtended by each component part of the letter, and every one knows that most eyes are capable of seeing more than 5. In Chapter III, dealing with diseases of the conjunctiva, the author reaches his own special subject, to the investigation of which he has given so much attention. The illustrations are infinitely better than in the preceding chapters, and this section is evidently written by one who has devoted himself to bacteriological investigation. Chapter IV deals with the cornea and sclerotic. A photograph shows the author's chair and headpiece for the localization of foreign bodies by means of the x-rays. Perhaps few surgeons will agree with the statement that "it is little use attempting to extract foreign bodies in the eye after three days, unless they are loose in the vitreous or embedded in the lens, as they become surrounded by lymph." The fifth chapter deals with diseases of the iris, ciliary body, and choroid, and describes the ordinary conditions met with. Chapter VI, dealing with diseases of the lens, occupies only fourteen pages, which is certainly not a large space to devote to this structure. After that the retina, vitreous, and optic nerve are discussed in one chapter, followed by glaucoma, disorders of ocular muscles, diseases of the eyelids and orbit. The whole of the operations on the eye are condensed into forty-nine pages, and, finally, there is an appendix. The book is nothing like so large as it looks, owing to a wide margin, large type, and a large space between each line. We are not particularly impressed with the book. It cannot be considered to compete seriously with the many textbooks already in existence, and, if it aims at being a cram book, it is too large. No doubt the author was limited in the space at his disposal, for we know enough of his previous publications to feel sure that he is capable of producing a book which would be more generally useful.

The effect of a want of balance in the muscles of the eye looms large in the minds of some people as a cause of neurasthenia and many other ills of the nervous system. Every one will agree that until recent years the subject was much neglected; however much the eye muscles were out of gear, no attention was given to them unless the want of parallelism of the eyes was sufficient to cause an obvious squint. A reaction came, and certain authors, notably in America, went to the opposite extreme, and made out that pretty well every disease to which the human frame is heir owed its origin, directly or indirectly, to some defect of the ocular muscles. Thoughtful men set to work to find out where the truth lay, and as usual it was found to be somewhere between the two extremes. Volumes have been written on the subject, but one of the most complete works is that written by Dr. LUCIEN HOWE, of Buffalo. Volume I of *The Muscles of the Eye* was published more than a year ago, and consisted of a description of the anatomy and physiology of the eye muscles. Volume II, which has now appeared, deals with pathology and treatment, and consists of five parts split up into numerous chapters and divisions. It contains 374 pages of text, and

² *Preventable Blindness*. By N. Bishop Harman, M.A., M.B., F.R.C.S. London: Baillière, Tindall and Cox. (1907.)

³ Oxford Medical Publications. *Diseases of the Eye*. By M. Stephen Mayou, F.R.C.S. London: Henry Frowde; and Hodder and Stoughton. 1908. (Cr. 8vo, pp. 400, 119 illustrations, and 8 coloured plates. 5s.)

100 more of bibliography, index, and appendix.' The book contains good material, and the facts are well and carefully arranged. It represents an enormous amount of work, and includes within its pages reference to all the work which others have done on the subject. No one who is interested in this branch of ophthalmology could afford to be without a copy, and we heartily commend it to our readers.

THE RAT PROBLEM.

The Rat Problem, by W. R. BOELTER,² deals with a question which has lately come prominently to the front in the domain of preventive medicine. The desire of the author is to enlist public opinion in the crusade against rats and other vermin, and thus pave the way for the passing of a bill drafted on the lines of the Danish Rat Law by the Incorporated Society for the Destruction of Vermin.

The first chapter deals with the natural history of the brown rat (*Mus norvegicus*), tracing its introduction into Europe from Asia in the eighteenth century, destroying on its march the less savage black rat (*Mus rattus*), and rapidly, owing to its great fecundity, becoming a serious pest. It is suggested that there are in this country at least as many rats as there are human beings, and on the moderate estimate that each rat does one farthing's-worth of damage daily by the destruction of food and other material, the annual loss is calculated to be £15,000,000. This figure has been arrived at by means of certain rat feeding experiments, and by systematic inquiry among land owners, farmers, shopkeepers, shipping, dock and colliery companies, and others.

Only one short chapter is devoted to the part played by rats in the dissemination of disease, but as the book has been written more for the lay than for the medical reader, the notice this branch of the subject receives is sufficient for the purpose in view. The channels of communication between the rat and man, resulting in the propagation of trichinosis and plague, are shortly described, and as regards the latter disease, while it is stated that the rat is not the only agent of dissemination, it is claimed that to disregard that factor would defeat any scheme for the stamping out or even the partial reduction of the disease.

Considerable space is devoted to the means for exterminating rats, and "the ruthless destruction of some of their natural enemies, the owl, the weasel, and kestrel," is deprecated. An interesting account is given of the numerous mechanical devices for exterminating rats, many of which are said to be very efficient in the hands of experts who are familiar with the habits of the animal. The use of chemical poisons for this purpose is not very strongly advocated; although seemingly a cheap method it is said that in practice it is found to be the most expensive, because it frequently entails the accidental loss of other life. An account is given of the more or less successful efforts of bacteriologists in this and other countries to find a reliable virus poisonous to rats and mice only. While it would seem that this quest has not yet been altogether successful, the author appears to favour Neumann's virus ("ratin"), partly because it is supplied in a form for convenient use by inexperienced persons. Favourable though the experimental trials with this virus appear to have been, the author doubts its power so far as transmitting the disease from rats which have been poisoned to healthy rats is concerned. Be this as it may, it is not surprising that when this or any other virus comes to be prepared on a commercial scale and sold by local tradesmen disappointing results should be obtained. Moreover, having regard to the possible risks attending the indiscriminate use of all such animal poisons, sooner or later it will become necessary to impose conditions upon their sale to the general public, especially in view of the recent unfortunate occurrence in the City of London recorded by Dr. Collingridge.

The book is attractively written, well illustrated, and is carefully calculated to serve its purpose.

² *The Rat Problem*. By W. R. Boelter. London: John Bale, Sons and Desimous, Ltd. 1909. (Fcap. 4to; 165 pages and 75 illustrations. 2s. 6d.)

ANATOMY.

In compiling this textbook of the comparative anatomy and development of the fetal membranes and placenta, Professor GROSSER¹ has undertaken a piece of work that was well worth doing and has performed the task exceedingly well. The text is written in the pellucid style in which occasionally a German can write, and it is admirably matched and illuminated by the numerous illustrations, mostly photographic, and the diagrams. It is thus an attractive book to read, and the author has at the same time been so successful in the judicial tone of his summary that the critic has no need to deal with the matter of his judgements. The descriptions and argument develop so smoothly, and the author is so careful to indicate the questions that remain unsettled and to describe the reasons of those from whom he differs, that his reader is not likely either to misunderstand him or to be entrapped into any false position. About a quarter of the volume is devoted to the history of the fetal envelopes, and in this, after a clear account of the processes in the easily observed Sauropsidae, Professor Grosser discusses the forms of development of the amniotic cavity in mammals and the early stages of their embryology. The rest is devoted to the subject of placentation, and in this, after an adequate description of the semiplacentae and of placenta verae in animals, he discusses in detail all the recent work that has been done on the implantation of the human ovum and its early development. In the course of the discussion the origin of most of the placental anomalies is indicated, and there is a section on the biology of the placenta which, for completeness' sake, one might have wished extended on the chemical side. As it is, the results of the important chemical investigations on placental metabolism, which have been fairly numerous, are only indicated, but perhaps the author might plead that he is an anatomist. Otherwise, the book is a satisfactory one, and the printer and illustrator deserve praise as well as the author himself.

NOTES ON BOOKS.

ALTHOUGH intended only for pharmacists, there is a good deal in *The Chemist's Annual for 1909*,² edited by Mr. JOHN HUMPHREY, which should be found useful by medical men. Suggestions with regard to details of treatment might at times be gathered from the Supplement to the *British Pharmaceutical Codex*; while in the additions to the *Pharmaceutical Journal Formulary* registered during the last two years may be found a great number of recipes for the preparation of elegant mixtures, pastes, and pills, such as crowd a modern chemist's shop.

Dr. W. T. BEEBY and Mr. E. REYNOLDS-BALL have furnished a very readable and practical guide to *The Levantine Riviera*.³ Every one who has travelled by railway between Genoa and Spezia must have been struck by the extreme beauty of the scenery of this narrow strip of coast between the mountains and the sea, as far as occasional glimpses between the innumerable tunnels allowed him to see it at all. This coast undoubtedly should and does attract many who require a sunnier and more southern winter climate than that of England, with less crowd, less fashion, and probably less expense than at most places of the Western Riviera. The little guide book seems to us, in its descriptions of Rapallo, etc., only to give the Eastern Riviera the praise which is really its due.

A more decorative exterior is the most obvious change in the edition of *Whitaker's Peerage, Baronetage, Knightage, and Companionage for 1909*.⁴ There are many who may be disposed to quarrel with the terms used in the title of the work, but few will cavil at its contents. These, as in former years, set forth alphabetically the names of all persons, whether male or female, who are deemed to have a right to a handle of any sort to their names, or who have been admitted by the reigning monarch to any one of the numerous Orders. The very useful introductory matter

¹ *Vergleichende Anatomie und Entwicklungsgeschichte der Eihäute und der Placenta mit besonderer Berücksichtigung des Menschen*. Von Dr. Otto Grosser, A. O. Professor für Anatomie im Wien. Wien u. Leipzig: W. Braumüller. 1909. (Sup. roy. 8vo, pp. 326; 210 Abbildungen im Text u. 48 auf chromolithographierten Tafeln. M. 10.)

² *The Chemist's Annual for 1909*. London: The Pharmaceutical Press. (Imp. oct., pp. 994. Price 5s. net.)

³ *The Levantine Riviera: A Practical Guide to all the Winter Resorts from Genoa to Pisa*. By W. T. Beeby, M.D., and E. Reynolds-Ball, F.R.G.S. London: Reynolds-Ball's Guides. 1908. (Fcap. 8vo, pp. 168; illustrations and a map. 2s. 6d.)

⁴ *Whitaker's Peerage, Baronetage, Knightage, and Companionage*. London. 1909. (Post 8vo, pp. 500. Price 5s.)

includes this year a glossary of official terms, from which the significance of a number of phrases frequently employed, but not always clearly understood, may be immediately ascertained. Information is given, for instance, as to the functions of little-known bodies and officers, such as the Court of Claims and the Clerk of the Chique. This reference work, in spite of the moderation of its size, is comprehensive and easy to consult.

MEDICAL AND SURGICAL APPLIANCES.

THE NEW TYPE OF NEWTON-ROENTGEN GENERATOR.

At the Sheffield meeting of the British Medical Association, Dr. Lester Leonard of Philadelphia brought forward some results of instantaneous x-ray exposures obtained with the aid of a closed magnetic circuit transformer, capable of producing a very large volume of secondary current through the tube. Subsequently, at the Amsterdam Congress of Radiologists, the inventor, Clyde Snook, also of Philadelphia, read a paper on this form of generator, and on that occasion Messrs. Newton and Co., of London, secured the right to manufacture these machines in this country. The Snook-Roentgen apparatus, for those who can afford to possess it, will greatly simplify x-ray procedure. No trouble can arise from induction coil or interrupters; and the output of the rays is absolutely controlled by the movement of a crank handle. It is the result of six years' careful study of the induction coil, the aim being—as with improvements of this induction coil itself—to suppress the inverse discharge as completely as possible and to increase the useful secondary current. The apparatus consists of two parts, one a dynamo or inverted rotary converter—serving the purpose of the interrupter in the ordinary installation in that it takes up continuous current from the main, and sends it out as alternating current—and the other an oil-immersed closed magnetic circuit transformer, deriving its primary low voltage current from the converter. But the essential point about the apparatus, which adds so greatly to its efficiency, is the arrangement by which the rectifying switch receiving the high tension secondary current from the transformer is maintained in synchronism by being mechanically attached to the axis of the dynamo or converter producing the primary alternating current. This mechanical rectifying arrangement, which makes it possible to utilize the full value of both phases of the current, overcomes a difficulty which radiologists have experienced for years. Practically the entire output of the closed circuit transformer is available, and there is no need to trouble about synchronism because the rectification takes place on the shaft of the generator, any variation in pace will affect both movements equally and simultaneously. Thus, while the best induction coils only give, perhaps, 20 per cent. efficiency, the Snook apparatus gives more like 90 per cent. A demonstration upon the top-side x-ray machine which Messrs. Newton have introduced showed that it was easily possible to adjust the current delivered to the tube up to 40, or even 60 milliamperes, indeed, to an extent beyond the power of any x-ray tube at present constructed to withstand. Nor was the easy adjustment limited to the higher outputs of electrical energy, for equal steadiness was obtained down to the fraction of a millimetre. The movement of a crank handle to produce the rapid delivery of any desired amount of unimpaired energy to the tube is surely the last word in simplicity. It may be added that this machine is probably the first electrical invention—at any rate, so far as medicine is concerned—to be manufactured in this country through the instrumentality of the new Patent Act. If it had not been for that piece of legislation the machines would undoubtedly have been imported from the United States. The apparatus is on view during January at Messrs. Newton's premises at Temple Bar, E.C.4, and those who are interested in x-ray work are invited to witness demonstrations, for which no special appointment need be made.

Antiseptic Chamber.

DR. R. FORBES OWEN, Streatham writes: May I be allowed to reply to your kind criticism on the light question contained in the article on my open-air chamber, published on December 5th, 1908, p. 1686? There will be a flood of light from large top lights in all the four corners of the roof; and again, any who desire to remain indoors during the evening hours, or in the day, may wish that they should really be necessary, and the caves serve a very important office in protecting the open-air panels, and the gallery also from the wind and rain, while allowing the air to freely circulate all throughout the chamber. A single child, for one can be built for as little as 45s. and so up to 12 beds in one chamber about 180s. are covered and sheltered.

MEDICAL INSPECTION AND AFTER.

MEDICAL TREATMENT OF SCHOOL CHILDREN

IN THE JOURNAL OF DECEMBER 26TH, 1908, p. 1869.

IN the JOURNAL of December 26th, 1908, p. 1869, appeared the text of the reports presented to the London Education Committee by a special subcommittee appointed to inquire into the whole question of the medical treatment of children attending public elementary schools in London, but we were not then able to deal with certain appendices to the majority report, of which we will now give some account.

In the course of its inquiry the subcommittee found it desirable to ascertain how far existing medical institutions would be in a position to meet the increased demands for the medical treatment of elementary school children expected to arise as a consequence of the institution of medical inspection. The elucidation of this matter involved not only questions as to the numerical sufficiency or the provision that is or could be made, but also the situation of the institutions, hospitals (general and special), free dispensaries, and provident dispensaries, in relation to the distribution of the population from which children attending elementary schools are chiefly drawn.

The committee first, in November, 1907, addressed a circular letter to hospitals in the county of London, but the information thus obtained showed that a wider inquiry was necessary. In consequence, on February 7th, 1908, the following circular letter was addressed to the authorities of hospitals, dispensaries, and kindred institutions:

Sir,—The Education (Administrative Provisions) Act, 1907, gives the Council further powers, and imposes new duties in respect of the medical inspection of children; and the question therefore of how far existing institutions do or can meet the increased demands for the medical treatment of children, has become of immediate importance.

The Education Committee, with the authority of the Council, have accordingly appointed a Special Subcommittee consisting of members of the Council and representatives of a necessarily limited number of outside institutions to inquire into the whole question of the medical treatment of children attending public elementary schools within the county.

The Committee are advised that the greatest difficulty experienced by the hospitals is in dealing with the large numbers of children who present themselves for treatment of the teeth or the eyes, dental diseases and errors of refraction being respectively the ailments for which treatment is usually desired. The Committee, with a view to making the fullest possible inquiry into these matters, are anxious to obtain further information from the hospitals and dispensaries of London in respect of these classes of cases.

I am accordingly directed to ask you to be so good as to supply me with the information asked for on the accompanying schedule, if possible by 14th February, 1908, viz.—(1) The number of children under 14 treated during the years 1906 and 1907 for various ailments of the teeth, distinguishing between treatment for measurement, for extraction of teeth, and (2) with similar information for the same period in respect of children treated for various affections of the eye, distinguishing between (a) errors of refraction, (b) actual diseases, (3) what accommodation exists for the treatment of children under (1) and (2) respectively above, and whether it would be practicable to treat larger numbers of children during the regular hours of work of the institution, or to make the institution under special arrangements outside the regular hours for the exclusive treatment of elementary school children.

The Committee desires me to express the hope that if it be found necessary to submit this letter to the Hospital Committee, arrangements will be made in the meantime for the preparation of the necessary information, inasmuch as it is desired that the return for the various hospitals and dispensaries of London shall be printed and submitted to them at their next meeting, which has been fixed for Friday, 21st February, 1908.

We reproduce the table in which the replies received were summarized by the subcommittee. We also give a map of the county of London showing the position of hospitals and dispensaries, which reveals, what is of course well known to every one who has given attention to the subject—that institutions for medical relief are very much concentrated in the central districts. The figures on the map show the number of children of school age in the various districts.

Among the appendices is a report made in November, 1907, by the Day Schools Subcommittee on the work of the medical officer. The report states that it was found that medical inspection created a demand for medical attendance, and that that demand did not produce a corresponding supply. It could not now be shown in full detail

that the health of many children was impaired, temporarily or permanently, for want of medical treatment. It could also be shown that, in a considerable proportion of cases, medical treatment was practically unattainable. The medical officer (Education) had a medical staff consisting of two full-time doctors, two half-time doctors, twenty-three quarter-time doctors, and thirty-two nurses under a superintendent. The whole of this staff was employed in inspectorial work alone. The report then gives some particulars of the number of children found defective in respect to vision, hearing, ringworm, teeth, and tuberculosis (external), and the committee states that the facts point to the general conclusion that there were two classes of cases which the hospitals found unmanageable: the mere weight of numbers seemed to prevent their dealing adequately with the very common forms of childish defects (vision, hearing, ringworm, teeth), while they had equal difficulty in dealing with chronic cases demanding prolonged treatment (tuberculosis). Up to the present time the powers of the Council had been limited to inspection. As a result of that inspection, many preventable but unremedied evils had been discovered, and fresh powers and fresh duties had now been laid upon education authorities by Parliament.

Following this report are memoranda and notes of evidence taken by the subcommittee under the heads (a) as to the teeth, (b) as to vision, (c) as to ringworm and favus, (d) as to suppurating ears and adenoids, and (e) as to tuberculous disease. The general conclusion as to the last-named has already been given in the JOURNAL, but is of so much importance that it may be here reproduced:

TUBERCULAR AND DEBILITATED CHILDREN SUITABLE FOR TREATMENT IN RESIDENTIAL CONVALESCENT SCHOOLS OF RECOVERY.—General.—For a number of tubercular children, especially those suffering from bone or joint disease, there is little in the way of prevention in the earlier stages, and the hospitals generally do most in relieving the urgent stages comparatively late in the disease. There are also large numbers of children with diseases causing much damage, such as small ulcers on the surface of the eye, troubles about throat, nose, or ears, which become most chronic, the children known as quite typical to every one who has sat on attendance committees, whose parents are quite anxious for their health, but who are the object of fair suspicion, dark-rimmed round the eyes, who do not sleep well at night, and on the other hand can hardly be wakened in the morning, will scarcely touch breakfast, often indeed are sick either before starting or even on getting to school, and are essentially the result of their environment, reacting on a delicate organization, and for whom the only hope of satisfactory escape from severe damage is removal from their surroundings for two or three or more months until health is re-established. All this class of children might be considered as suitable for treatment in residential convalescent schools.

Under the heading (f) "provision for treatment," notes of evidence given by Mr. C. H. Warren, representing the Provident Medical Association, and Mr. T. Hancock Nunn, representing the Juvenile Benefit Society, are given.

PROVIDENT DISPENSARIES.

Mr. Warren stated that there were 38 provident dispensaries and medical clubs in the London County Council school area; 18 of these were under the control of the Metropolitan Provident Medical Association, the others were independent institutions, more or less in touch with and represented on the London Provident Dispensaries Council. Attached to these dispensaries there were upwards of 320 general medical practitioners and dental surgeons. About 110,000 persons were enrolled as provident members of these institutions, some 50,000 being children. In return for regular payments on the principle of insurance, medical treatment was given to members whenever required. Each member joining selected from the staff his own medical attendant who became the family doctor. Patients suffering from special ailments requiring hospital or other treatment were usually sent to the most suitable institution. The conditions for medical treatment by the Provident Medical Association were that persons should join while in health—children being only admitted with a parent or guardian—and that payments should be kept up during health and sickness. Medical attendance was given at the dispensaries, in the doctors' surgeries, and in the homes of the patients. The benefits of provident dispensaries were limited to those who were unable to pay ordinary medical fees. The usual rates of payment were 6d. a month for adults and 2d. a month for children, 1s. 6d. a month being the maximum charge for a family. The object of provident dispensaries was to provide through

the general practitioners medical treatment for ordinary ailments of working-class families. They were not at present equipped for dealing extensively with cases of dental caries, errors of refraction, suppurating ears, etc., these being usually treated, if at all, in general or special hospitals to which they were often sent on the recommendation of the dispensary medical officer. To deal with these cases satisfactorily it would be necessary to enlarge the equipment of the dispensaries, and in some cases, to make special appointments on the staff. A start in this direction could be made without much delay in the dispensaries of the Metropolitan Provident Medical Association, and no doubt the system would be extended through the influence of the London Provident Dispensaries Council to the other provident dispensaries of London.

In reply to the question whether the Provident Dispensaries Council could arrange for the medical treatment of children not members of a provident dispensary and unable to pass a medical examination, Mr. Warren said that the provident dispensary only dealt with those persons and families who had made provision for medical treatment by joining before illness overtook them. The scale of fees charged was in every case designed on the principle of insurance, and not as a payment for an actual illness. But in the majority of provident dispensaries, including all those controlled by the Metropolitan Provident Medical Association, provision had been made for persons requiring immediate treatment, who paid a special entrance fee with a view to their remaining as provident members after the particular illness. An arrangement could be organized by the provident dispensaries in co-operation with the London County Council for the treatment of children not members of a provident dispensary—so long as the interests of the general practitioners were safeguarded, and an endeavour was made to enrol the parents of such children as provident members. For such cases of special treatment payment in accordance with a fixed scale would have to be made either by the parents of the children or, failing that, by the London County Council. At present the Metropolitan Provident Medical Association only dealt with a very limited number of children, but the system was very elastic and was designed to cover London working-class medical treatment.

To carry out medical treatment of school children would require the co-operation of the body of general practitioners in London and would entail the development of many special forms of treatment—for instance, in cases of weakness in the teeth, eyes, and ears of children, which had not up to the present been needed or practicable. In co-operation with the London County Council the Metropolitan Provident Medical Association and the London Provident Dispensaries Council would endeavour to make their organizations meet the required want, and open dispensaries or clubs in working class districts. This would require time to accomplish, and must be preceded by an arrangement securing the services of a much larger body of medical practitioners than was at present attached to the dispensaries. Such an arrangement could probably be made, and would be immediately attempted if the London County Council gave encouragement. The advantages would be that a system would be created on a natural basis, in which parents, the medical profession, and public spirited persons of the class now managing the hospitals, would all take a share, and be interested in securing satisfactory medical arrangements for children, on the footing that the bulk of the cost was found by provident subscriptions or parents, in the same manner in which the English working classes were accustomed to provide for their own sickness, through subscriptions to friendly societies, and that the whole responsibility for the children's health and the great cost of their medical attendance should not be thrown on the local education authority and the rates. It would be better for the community that a sound general system should be adopted at first, although it might only be possible to bring it gradually into complete order, and adapt it to the wants of the families as experience demanded.

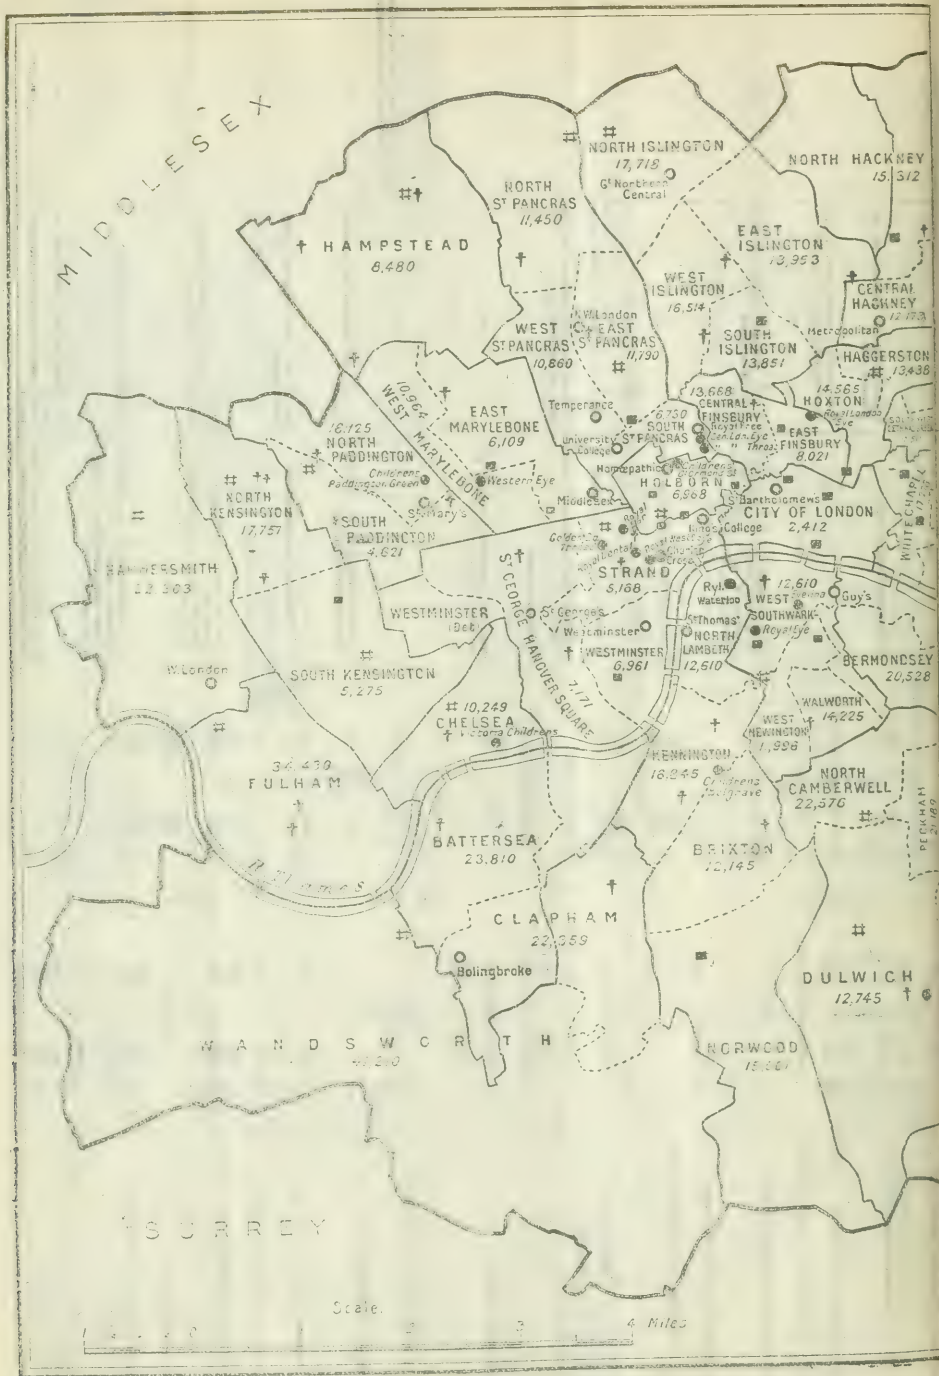

JUVENILE BENEFIT SOCIETY.

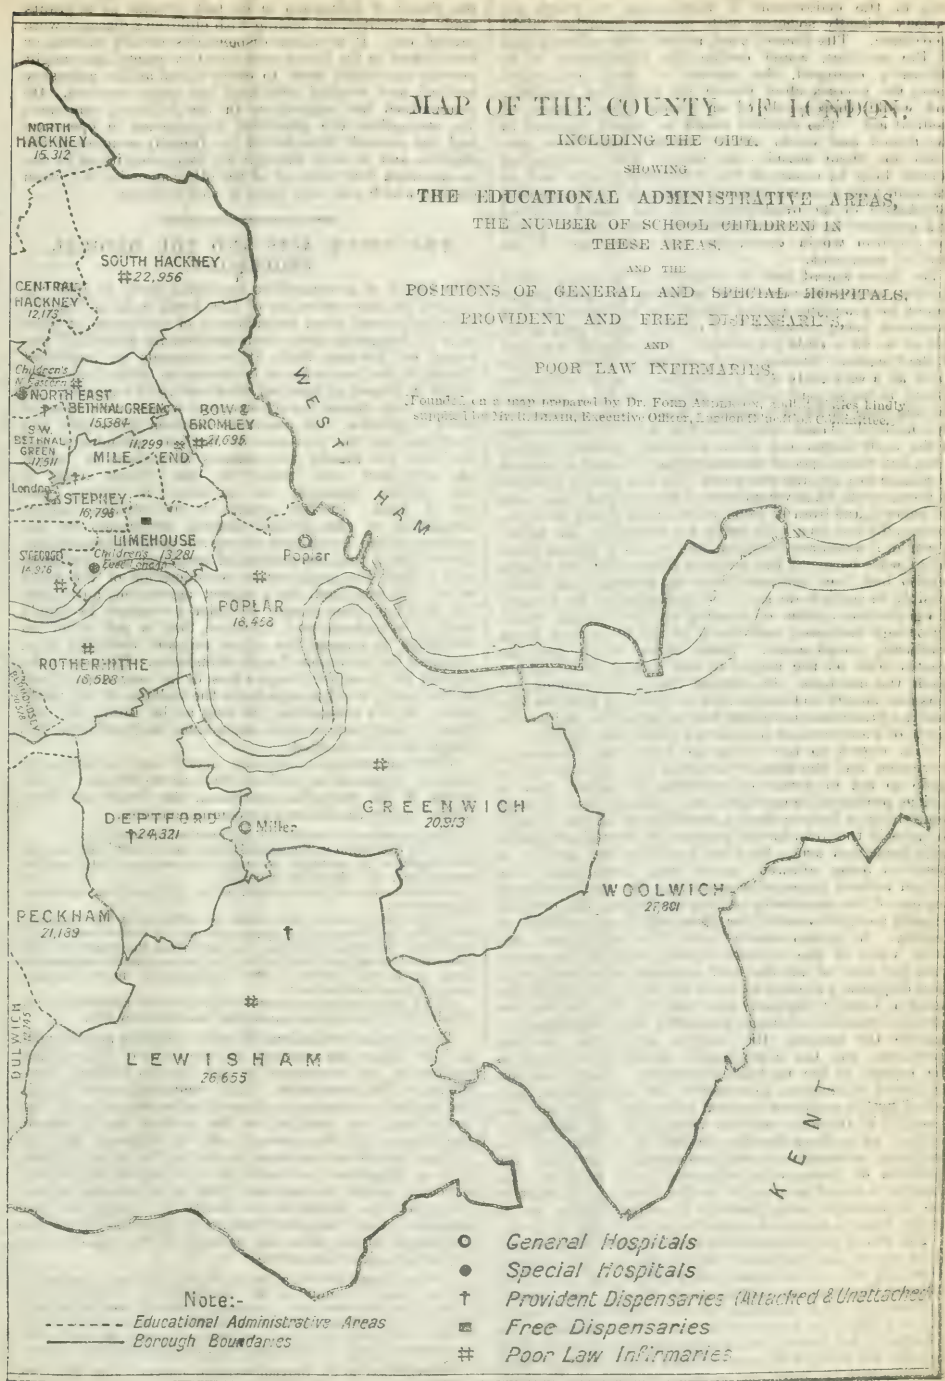

Mr. Hancock Nunn considered that the Juvenile Foresters' movement was capable of great extension, particularly in the direction of the development of

Summary of Replies from Hospitals, Dispensaries, and other Institutions.

Name of hospital, dispensary, or institution.	What number of children under 14 were treated during the years 1906 and 1907 for various affections of the teeth, distinguishing (a) for preservation, (b) for extraction of teeth?		What number of children under 14 were treated during the years 1906 and 1907 for various affections of the eyes, distinguishing (a) errors of refraction, (b) actual diseases?		What accommodation exists for the treatment of children under (2) and (3) respectively?	Would it be practicable (a) to treat larger numbers of children during the regular hours of work of the institution, or (b) to make arrangements outside the regular hours for the exclusive treatment of delinquent school children?	Remarks.

[illegible]

outside dispensaries, and suggested that the Council should help in the endowment of dispensaries to which the various friendly societies with juvenile branches might contribute. The Council's aid, added to the subscriptions of the societies, would enable the dispensaries to be efficiently equipped, the absence of such equipment being the parents' chief reason for preferring hospitals, and would thus result in an almost ideal system of medical aid. The children would be drawn together in the school, and would receive medical attendance provided for them outside the school, thus encouraging mutual help by means of the Foresters' Courts, and at the same time securing medical inspection by dispensaries established in the neighbourhood of the school endowed and equipped by the local authority, but towards which the children would contribute the actual cost of the medical treatment.

Mr. Nunn stated that in Hampstead as many school children as possible were urged to belong to a good benefit society for providing against illness, the necessary medical treatment being provided by a medical officer paid at the rate of 4s. 4d. a child per annum. The principle was that of the Foresters' Society, which enabled children to join a court at a very early age and receive a small allowance during sickness and medical attendance for a payment varying from 2d. to 6d. a month. Each court selected its own medical adviser, who could deal with children's teeth in the early stages, and when necessary perform extractions, but where special treatment was required a letter of admission to a hospital was given. The fees paid by children at Hampstead, all of whom were of the working class, were 2d. below 5, and from 4d. to 8d. from 5 up to 14 and upwards. Parents did not, as a rule, apply for treatment for teeth; it would, if necessary, be given, and up to a certain point the expense borne by the society's dispensary: no special dentist had been appointed, but an arrangement might possibly be made to do so. The institution by the Council of a gratuitous system of treating children's teeth would discourage members, and result in the movement being practically swept away. Slate clubs, which had the greatest hold on the people in the poorest parts, did not reach the children. He desired that the provident dispensaries should be brought into co-operation with the distinctly educational movement for the formation of juvenile courts of Foresters and Oddfellows within the schools.

With regard to the extent to which the dispensary movement and the friendly societies movement could be made to act in direct co-operation, he stated that in various provincial towns there had already been formed some thirty or forty medical associations of all the friendly societies in the town for the purpose of providing medical attendance and drugs for their members, the families of members being allowed to join the dispensaries thus formed without necessarily qualifying for membership of any one of the societies by passing the doctor. The juvenile friendly societies existed for those who were certified as healthy. A system which linked the educational and social value of the juvenile friendly societies movement with the care of all the sick members of a family at a local dispensary seemed to meet the need with which the London County Council was faced. In London the juvenile branches of friendly societies were unprepared to provide the nursing, the surgical appliances, surgical operations, and the convalescent treatment indicated in the reports of the medical inspectors. They, however, expressed willingness to consider the new problem presented by the results of medical inspection. The juvenile branches of friendly societies were as a rule financially well off, so much so that the question of dealing with the surpluses accumulated was constantly attracting the attention of those who organized such societies. He thought it would be possible in the future so to organize the dispensaries and juvenile friendly societies as to enable them to deal with a very large proportion of cases.

The School Care Committees were in touch with associations which had for their object the care of children, especially of sick children. On most of the Care Committees the Charity Organization Society was largely represented, and members of the Children's Country Holiday Fund, the Invalid Children's Aid Association, the Children's Aid Society, and similar associations were to be found. He thought it certain that a combination of these societies with the provident agencies might deal effectively

with the whole problem, especially if the suggestions of the Board of Education in its last circular as to grants made to institutions dealing with children's diseases were carried out. If provident dispensaries already existing or established in the future were aided by grants, they might provide eventually near to every school all the necessary medical and surgical treatment the cases required. He summarized his suggestions in the following sentence: To strengthen the provident dispensaries in operation and the juvenile branches of the friendly societies of the district, and to seek through our care committees for the co-operation with them of all the other agencies in a given district which deal with cases of sick children.

THE TRUCK ACTS AND THE MEDICAL PROFESSION.

THE report of a committee appointed early in 1906 "to inquire into the operation of the Truck Acts, and to consider and report what amendments of extensions of those Acts or changes in their administration are desirable" was issued on January 2nd. It recommends an important change in the law so far as it relates to deductions from wages in respect of medical attendance and expenses. As the law now stands, deductions from wages are subject to strict regulation, but contracts between employers and workmen for the provision of medical attendance and medicine are among the matters in respect of which an exception was made in the Truck Acts to the general principle of payment in money and not in kind. In the report of the Medico-Political Committee of the British Medical Association on the working of the Truck Acts as regards medical attendance¹ it was stated that the position of employer and workman now is that the employer, in consideration of the sums which the workman, by a signed agreement, authorizes him to deduct from wages, is under a contract to supply medical attendance and medicine, but is not under an obligation to expend the whole amount deducted from wages in the provision of such attendance. He may make a profit for himself or incur a loss, or he may devote part of the money to other objects for the welfare of the workmen. He is a contractor. So long as he fulfils his contract by supplying medical attendance and medicine, his obligation is discharged.

With the object of ensuring that if any deduction for medical expenses be made, it shall all be devoted to the needs of the particular workman, the Truck Act Committee makes the following recommendations:

That in respect of medicine and medical attendance:

(a) The exception in Section 23 of the Act of 1831, empowering the employer to contract to supply his workmen with medical attendance, etc., should be repealed;

(b) The doctor or doctors must be the choice of the workmen themselves;

(c) The contributions may either be collected by the workmen and paid over direct to the doctor, or may, at the request of the workmen, be deducted by the employer from the wages for the purpose of being paid over either to the workmen's representatives or to the doctor under arrangements made between employers and workmen;

(d) No commission on account of the services rendered by the employer in this transaction should be allowed by law.

These recommendations in some respects accord with, and in others are contrary to, the views of the medical profession, as expressed by the Medico-Political Committee of the Association. That committee stated that in the medical profession it appeared to be generally felt that compulsion was justified on the ground that it was to the interest of the general body of workmen and the average individual workman, regarding his life as a whole, that an obligation to consent to a deduction for medical expenses should be imposed. But in recommending that the workman should be at liberty to choose his own attendant, the Truck Act Committee appear to have taken cognizance of the following passage in the report of the Medico-Political Committee:

The conclusion arrived at by the British Medical Association, as the result of inquiries and deliberations extending over three years, has been that, generally speaking, medical attendance under contracts of any kind will be most satisfactorily given when the individual patient is allowed, so far as the circumstances of the district permit, to choose his own doctor.

¹ SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL, June 20th, 1908, p. 426.

THE COMPARATIVE ANTISEPTIC VALUE OF DISINFECTANTS.

THE methods hitherto employed for the standardization of disinfectants have been confined almost entirely to the determination of their direct germicidal action when the bacteria have been exposed to the action of solutions or emulsions of the disinfectant. To all of those methods objection has been made on the ground that the germicidal action was determined under conditions which did not correspond to those in actual practice when disinfection was carried out on a large scale. Dr. S. B. Schryver and Dr. R. Lessing, who have recently undertaken a fresh investigation, gave an account of their results before a meeting of the London Section of the Society of Chemical Industry on January 4th. Their communication was entitled "A Physico-chemical Method for Comparing the Antiseptic Value of Disinfectants."

Dr. Schryver, who read the paper, said that of the various methods proposed for determining the antiseptic value of the numerous products, proprietary and others, which had in recent years been employed for the purposes of disinfection, perhaps the best known were the "thread method" of Koch, the "garnet method" of Krönig and Paul, and the method, which had been extensively employed in this country, of Rideal and Walker. In the Rideal-Walker method definite small amounts of broth culture of the same species and age were added to a constant volume of a disinfectant solution. A series of trials were made with varying concentrations of the disinfectant to be tested, and of pure phenol under similar conditions, and the relative concentrations necessary to complete germicidal action within equal periods of time was thereby determined. The ratio of the reciprocals of those concentrations was termed by Rideal and Walker the "carbolic acid coefficient," and was regarded by them as the standard of disinfecting power. Various objections had been made to this method, chiefly on the ground that the actual test for disinfection was carried out in the absence of organic matter other than that present in the disinfectant and the minute amount introduced by the bacterial culture, and the conditions of the trial were not therefore entirely analogous to those under which antiseptics were ordinarily employed. Somerville and Walker had endeavoured to remedy that defect by carrying out the disinfecting test in the presence of known quantities of added organic matter, such as protein and starch, and had in some cases obtained widely different numbers for the carbolic acid coefficient. The addition of organic matter could act in different ways with different disinfectants. In some cases—as, for example, in that of permanganate—the disinfectant could be directly destroyed by acting as an oxidiser to the organic matter; in other cases the disinfectant could be dissolved by the organic matter and thus removed from solution and its sphere of activity, an action which was conceivable when disinfection was carried out in the presence of fats by substances soluble in such organic solvents. A still more complicated case was that in which absorption of the disinfectant by the organic matter took place, a process which probably accounted for the behaviour of certain antiseptics recently investigated by Ehrlich and Bechhold. In all such cases the addition of organic matter would considerably lower the carbolic acid coefficient. Nor need such a lowering of the coefficient always indicate a diminished practical value. It was not possible, for example, that the disinfectant might be absorbed by solid matter; if the latter were the material required to be disinfected, it would, after a higher percentage of the disinfectant than the latter, in which case a lowering of the carbolic acid coefficient by the addition of organic matter should denote an increased practical efficiency. One more action of organic matter deserved consideration: Many of the more recently introduced disinfectants were emulsions, and it was generally admitted that their efficiency depended to a great extent on the degree of emulsification, for the addition of organic matter might either accelerate or inhibit the rate of de-emulsification, and thus, in a purely physical way, either decrease or increase the practical value. The problem raised by the introduction of organic matter was therefore one of great complexity, and as the mere

germicidal value as indicated by the various methods already mentioned was regarded as an insufficient test of the practical efficiency of an antiseptic, the authors suggested that a new method might throw some further light on the question. The rate of chemical change produced in a "substrate" by bacterial infection might be regarded as a measure of the vigour of the growth. By introducing substances inimical to the bacteria the rate of growth might be inhibited or even entirely arrested. The principle of the method of the authors depended essentially upon the measurement of inhibition produced when varying quantities of an antiseptic were added to an infected medium, and comparing those quantities with the amounts of phenol or any other standard disinfectant which would produce the same result. Of the chemical changes produced by bacteria, those of protein degradation or conversion of dextrose into lactic acid both lent themselves to chemical measurement. A measurement of the rate of putrefactive change in a gelatine-peptone substrate had been already carried out by one of the authors of the paper.* In that case a meat essence was infected with putrefying liver, and the nitrogen determined in the filtrate from the precipitate produced by adding a given volume of tannic acid mixture to a given volume of the medium removed from the main bulk after different intervals of incubation. This purely chemical method involved a relatively large amount of labour and was impracticable, but it was necessary to measure the rate of change which took place in different concentrations of an antiseptic, owing to the large number of analyses involved. Fortunately, the chemical change, in the case of protein degradation at any rate, closely corresponded to certain changes in the physical properties which could be readily and accurately measured, and in the method now brought forward the electrolytic conductivity had been taken as the index of chemical change. That physical property had already been employed for studying protein changes, notably by Sjöqvist, Oker-Blom, and Bayliss. The medium used in the author's experiments had been either gelatine-peptone or sodium caseinogen-peptone mixture containing about 5 per cent. of gelatine or sodium caseinogenate—that is, caseinogen dissolved in the requisite amount of sodium hydroxide—and 1 per cent. Witte's peptone. In all cases a mixed infection by faeces had been employed, as it was found to produce a much more rapid change in the substrate than was produced by the inoculation with a pure strain, probably owing to the fact that the action of the different species was specific, some degrading the protein to albumoses or proteoses, others acting only on those latter bodies, and others again only on amino-acids, as shown by Nawiasky. A similar method of infection had also been employed by Mr. Wynter Blyth. The relationship between electrolytic conductivity and protein degradation had already been determined by Bayliss in his investigations on the action of trypsin on caseinogen, where he found that the curves representing the conductivity of the caseinogen solution in different stages of digestion and the nitrogen in the filtrate from the tannic acid precipitation were very similar in form. An experiment was carried out to determine the influence of varying quantities of antiseptic on the form of the conductivity curve, and it was found that no putrefaction took place within four days, when the concentration of the phenol reached 0.1 per cent. A concentration of 0.05 per cent. was, however, insufficient altogether to stop putrefaction within that period, although it considerably impeded it. Caseinogen solution underwent a small change on incubation, even in the absence of putrefaction; the alteration in conductivity was, however, small, when compared with the changes produced by putrefaction. For that reason the gelatine-peptone mixture was to be preferred when testing the efficiency of antiseptics. In that latter medium the changes were small. The addition of mercuric chloride diminished the resistance of the substrate; formalin, on the other hand, increased it, owing probably to its capacity to enter into chemical combination with amino-derivatives. The disinfectants themselves also exerted sometimes small changes when present in large quantities, owing to their acid or basic characters. In no case, however, could such changes be mistaken for putrefactive alteration. The

* Schryver, Report No. 1, Inspector of Foods Department, Local Government Board.

factors concerned in the process of disinfection were so complex that the authors had for the present avoided the use of the word, "sterilization" in their description of the suggested methods. Nor had they attempted so far to express any numerical relationship when comparing the antiseptic value of the different disinfectants examined. There were, however, various methods by means of which such a relationship might be fixed; the most feasible would be to determine the relative quantities of the disinfectants which were just necessary entirely to inhibit putrefaction during a given interval. In their experiments no change was produced in the substrate when phenol was in the concentration of 5 parts per mille, although a considerable amount took place with 2.5 parts per mille. The amount necessary for total inhibition lay somewhere between those limits. By taking a larger number of dilutions those limits could be considerably narrowed and the relative amounts just necessary to inhibit putrefaction within a given time ascertained. The method suggested had many advantages, notably the small amount of time and labour involved and the simplicity of manipulation. It was furthermore adaptable to a large number of conditions, varying substrates and disinfectants in different physical forms, such as powders, emulsions, or organic solvents. It was hoped that that wide range of applicability would render the method acceptable to those engaged in the examination of antiseptics.

Dr. WILLIAM DRENFES (New York) asked if the authors of the paper had made any comparative tests between their method and that known as the Rideal-Walker. At first sight the method described by the authors seemed complicated.

Dr. SOMMERFELD said he would prefer to read the paper first before discussing it in detail, and he was followed by Mr. WYNNER BLANCH, who pointed out that the method gave high results for substances which were regarded at the present time as poor disinfectants. That might be because the old method of testing was wrong; but it was for the authors to prove their method was right.

Dr. RIDEAL said that the paper had opened up a new field of work. He thought the method was applicable to the determination of questions concerning preservatives and antiseptics. In his opinion the data were not sufficient to ascertain whether the solutions were of uniform resistance. He considered that it was better to measure the amount of change by some chemical rather than by any physical method. He felt a doubt as to what was really meant by the difference in the conductivity of solutions. He criticized the method of the authors in using faeces of unknown origin containing "a mob of organisms" of different kinds. It was difficult to ensure that any given sample of faeces contained the right amount of bacteria in the right proportion to grade the gelatine in the way suggested by the authors. That must be considered before the test could be regarded as a practical one. He himself and Dr. Walker had never put forward their method as a means of determining the way in which disinfection did its work; their method simply enabled the manufacturer, the buyer, and the seller to see that they were getting an article supplied according to original sample; it was a commercial method to judge whether an article was up to specification.

Dr. DOWFIELD doubted whether there was any possibility of finding a test for disinfectants perfect from an academic as well as from a practical point of view.

Dr. LESLIE, who replied, said that the method he and Dr. SCHRYVER advocated would be found on comparison with other methods to be most nearly in correspondence with the conditions of actual practice. As in practice pure cultures never had to be dealt with, ordinary faeces had been used.

A SOCIETY for the reduction of infant mortality has been founded at Moscow.

UNDER the will of the late Mrs. Frances Roget, of Maida Hill, the National Society for the Employment of Epileptics, and the National Hospital for the Paralysed and Epileptic, each receive a sum of £1,000; a further sum of £500 going to the Home for Epileptics at Muggill.

MR. ALEXANDER ROBB, M.B., M.P., C.M., has been appointed Medical Officer for the Counties of Midlothian, Linlithgow, and Peebles, in succession to the late Dr. Brodie. Dr. Robb has been medical officer of health for the Burgh of Paisley since 1901.

LACTIC FERMENTS FOR PRODUCTION OF SOUR MILK.

In consequence of the demand which has arisen for sour milk corresponding to the Bulgarian "yoghourt," a number of firms have placed on the market preparations of the bacteria necessary for its production; we have received several of these for examination, and the results of the tests carried out are given below. All but one of the preparations are in the form of tablets, and are intended to be taken by themselves, in addition to their employment in souring milk, for the purpose of obtaining a good growth of lactic acid bacilli in the intestine.

The samples examined, and the principal parts of the directions given in each case were as follows:

Fermentacetyl Tablets.—Prepared by the Pasteur Vaccine Co., Paris: English Agents, The Anglo-American Pharmaceutical Co., Ltd., Firth Road, Croydon. Directions: Boil the milk for 3 hours, remove film from surface, cool to 40° C. (104° F.), add 10 to 12 tablets crushed, to each pint, maintain at 40° C. for 10 to 12 hours. Sample received, February, 1908.

Lactobacillus Tablets.—Prepared by la Société le Ferment, Paris. Directions: Boil the milk for 10 minutes with stirring, cool to 38° C. (100° F.), add 3 tablets, rubbed down, to each pint, maintain at about 38° C. for 10 to 12 hours. Sample received, November, 1908.

Opportunists' Cultures in Tubes.—Supplied by Messrs. Oppenheimer and Co., Ltd., 119, Queen Victoria Street, London, E.C. This is a liquid preparation, contained in hermetically sealed tubes, the amount in one tube being intended for one pint of milk; the mixture to be kept at 40° C. for 8 to 10 hours. Sample received, November, 1908.

Salein Tablets.—Supplied by Messrs. Allen and Hanbury, Ltd., Lombard Street, London. Directions: Boil the milk, cool to 40° C., add 3 tablets, crushed, to each pint, set aside in warm place for 6 or 8 hours. Sample received, December, 1907.

Thick Tablets.—Supplied by Mr. W. Martindale, 10, New Cavendish Street, London, W. Directions: Boil the milk for 1 hour; cool to a warm blood heat; add 2 tablets, crushed, to each pint, maintain at the same temperature for 6 to 10 hours. Sample received, November, 1908.

For purposes of comparison, a temperature of 40° C. and a time of ten hours were employed in all cases. It has been pointed out in a recent article by Dr. R. W. Allen (BRITISH MEDICAL JOURNAL, November 23th, 1908; p. 1605) that it is highly desirable to keep the milk at or near boiling point for an hour before sowing it with the lactic bacilli; two series of tests were therefore made, in one of which the milk had been brought to the boil and then allowed to cool, while in the other it was brought to the boil and then kept in a boiling-water bath for one hour and subsequently cooled. The lactic acid formed was ascertained by titrating a portion of the milk with standard alkali solution. The milk employed at first was the ordinary supply of one of the large dairy companies in London. This was practically neutral to begin with; a portion of it was incubated at 40° C. for ten hours, and was then found to contain 0.04 per cent. of lactic acid; another portion was heated to boiling, then cooled, and incubated at 40° C. for ten hours, and was then found to contain only the same negligible trace of acid that was originally present. A portion of the milk which had been boiled was then treated with each of the preparations named above, using the proportions directed: portions of the milk that had been kept at boiling point for an hour were similarly treated, and the whole incubated for ten hours at 40° C. The acidity developed in each was then ascertained by titration, and the results are given in the columns headed I in the table. As the results in most cases were lower than was expected, the remainder of the milk cultures was set aside for a further twelve hours: for this second period the temperature was allowed to fall gradually from 40° and for a considerable part of the time it was about 10° C. The acidity of the different specimens was then again determined, and these results are given in the columns headed II. The plain milk so treated developed 0.26 per cent. of lactic acid; and the milk that had been boiled but had received no addition showed 0.03 per cent.

Another lot of milk was obtained from a country dairy, and carefully tested to prove the absence of preservatives; this was heated to boiling; and kept in a boiling-water bath for an hour. A further series of incubations at 40° for ten hours was made with this; the results are given in the column headed I A.

Percentage of Lactic Acid Produced.

Sample.	Milk brought to boil only.		Milk kept at Boiling Temperature for 1 hr.			
	I.	II.	I.	II.	I.	II.
	10 hrs.	22 hrs. (partly cold).	10 hrs.	10 hrs.	22 hrs. (partly cold).	22 hrs. (partly cold).
Fermentacetyl tablets ...	0.00	0.10	0.00	0.00	0.00	0.15
Lactobacilline tablets ...	0.00	0.05	0.00	0.02	0.10	0.10
Oppenheimer's cultures ...	1.02	1.10	0.75	0.96	0.98	0.98
Sauvignin tablets ...	0.04	0.23	0.03	0.07	0.21	0.21
T.H. diane tablets ...	0.00	0.09	0.03	0.27	0.28	0.28

Some irregularities are shown by the results of different tests on the same product, and this appears to be due to variations in the individual tablets and cultures. The actual formation of curd was approximately proportional to the acidity found by titration. The product was agreeable to taste, and free from bitterness in each case.

THE HISTORY OF THE ELEMENTARY SCHOOL CHILD.

VI.—SCHOOL INSPECTORS.

Nowhere in the school machinery is there such overlapping as in the inspection of schools, and nowhere is there more need for reorganization. There seem to be two great faults in the choice of inspectors: in the first place nearly all are men, and in the second they are chosen for their academic attainments rather than their practical knowledge of teaching. Though many inspectors have had a distinguished university career, it may safely be asserted that only in most exceptional cases have they taught in schools themselves. It follows that they are not qualified to criticize and direct work of a special character beset with such peculiar difficulties as that in the elementary schools. Education authorities draw up syllabuses and frame a general plan, but it is for the inspectors to see whether it works well or ill, to see that it is modified to suit different conditions prevailing in different neighbourhoods, and to suggest alterations, until some really practical scheme is arrived at. At present the inspectors are the reasons why teachers, often exceedingly capable and intelligent, often fall of initiative and interest in their schools, relapse into a dull programme of routine work, because their desire to make the time-table more suitable and more interesting to their classes is not understood, or is misunderstood by the inspectors.

The inspectors themselves—in London, at any rate—are over-inspected, and each has so many schools to get through in the year that if he were to spend time trying to understand the different points of view of the school teachers he would never get round. He also, perhaps, has the fear of being hauled over the coals by his superior officer, for subinspectors do much of the actual work of inspection, while the inspectors spend much time in office work. In London there are 24 school inspectors and subinspectors under the London County Council; 22 of these are men and 2 are women. The staff of school inspectors appointed by the Board of Education for England and Wales numbers nearly 250, of whom over 150 are subinspectors. They are almost all men. These gentlemen, both those appointed by the Board of Education and those appointed by the London County Council, base their reports on the schools on a particular standard of excellence to be attained by the children in such subjects as reading, writing, drawing, and needlework. A child who does not come up to the standard gets a black mark, and the teacher whose class does not produce results which satisfy the inspectors likewise gets a bad report. It does not matter how the children's eyes and brains are strained and forced in the attempt; nothing matters but the net result in fine stitches and pen-strokes. We all know that some children can never sew or write neatly, however good they may be at other lessons, but such idiosyncrasies are not taken into consideration. Indeed, the injury to eyesight has been so great in the past that such pressure is now forbidden in the infants,

departments; there is, however, far too much work done for show purposes at the expense of practical and sensible instruction. Here and there a progressive head teacher allows the girls to mend their clothes in school, but this can only be done outside the time set apart for specimen sewing. Could any other results be possible when men are appointed to posts which necessitate the inspection of needlework? The women teachers who are content to carry out their duties to the letter—and naturally they are in the majority—openly say that they prefer men inspectors to women because, provided they can force these mechanical results out of the pupils, they satisfy the inspectors. On the other hand, those teachers who have the practical training and real welfare of their pupils at heart, and do not wish to sacrifice their sight to the accomplishment of very fine work the uselessness of which is only too obvious, incur the displeasure of the inspectors. In this respect the teachers have a real grievance; the reports made by the inspectors on the teachers are confidential, and as the latter never see what has been said of them there is always a risk of injustice to teachers who may have definite views on the subject of education which, however reasonable, may clash with the personal views of the inspector.

In justice to the ratepayer, to the teacher, and to the elementary school child, the present system of selecting school inspectors should be reformed. The appointments should cease to be a mere piece of patronage extended to men who have taken what is called a good degree, and have influential friends. Candidates should be required to produce evidence that they have studied the art of teaching theoretically, and have had practical experience of the work in elementary schools. In Bulgaria, where a very complete and efficient system of State education has been established, the inspectors are chosen from among former professors of high schools who have had a university education, and have distinguished themselves by their contributions to pedagogical literature, and from among the teachers in primary schools who have taught for at least five years, and have passed the examination for the post of inspector. Similar regulations are greatly needed in this country, and would work a very salutary reform.

LITERARY NOTES.

Among other interesting articles in the current number of the *Cambridge Magazine* is one by the Dean of Canterbury on the famous editor of the *Times*, John Thaddeus Delane. Dr. Wace, who was one of his most trusted contributors, tells that Delane in training himself for the profession of a journalist, was not only called to the Bar but "attended the hospitals for some terms." Delane was always fond of medical and surgical knowledge, and he more than once mentioned to Dr. Wace his experience in Paris under Magendie. To the general knowledge thus acquired, Delane owed much as an editor. Almost alone among newspapers, the *Times* has, as a rule, not only dealt intelligently with medical matters, but has been careful to exclude from its columns the sensational rubbish about supposed new discoveries and mythical triumphs of the healing art with which the most "enterprising" of its contemporaries seem to take a pleasure in misleading their readers. *Quidquid Græcia mendax audit in historia* would seem to be prophetic of the irresponsible manner in which certain halfpenny papers of the present day deal with everything relating to medicine.

In a note contributed to the *Progress Medical* of December 26th, Dr. Cornet deals with the food of the Gauls. Among the early Gauls, as among the Germans, he says, the dietary consisted largely of milk and the produce of the chase, such as boars, reindeers, aurochs, etc. Even human flesh was eaten, probably when animal food was scarce. Little is known about Gaul before Caesar's day. Varro speaks highly of their ham and their sausages. The Gauls loved boiled meat, and boiled oats or porridge formed an important part of their diet. According to Cornet bread was made by the Phœocians or early inhabitants of Marseilles nearly seven centuries before Christ. Leavened bread, however, did not come into use before the time of the Roman dominion, and then only among rich folk. In the Frankish period the baker's shop began to take the place of family baking, especially in towns. The early Gauls, at least those in the interior, did not know

wine; the beverages in use were beer and hydromel. Both these drinks were known to other peoples by other names from the most remote antiquity. In the year 365 after the foundation of Rome, according to Pliny, an enterprising Etruscan trader introduced wine which pleased the Gauls so much that they forthwith determined to raid the country from which the delicious drink was produced. This led to the invasion of that part of Italy which the Romans called Transpaduan Gaul. Before the Roman conquest the Gauls, like the Scythians, Scandinavians, and other savage peoples, drank out of human skulls. After the Roman conquest they became more civilized in their manners, and their diet became gradually modified.

We learn from the *British Esperantist* for January that between August 5th and November 5th, 1908, 18 new Esperanto societies were founded in America—17 in the United States and 1 in Mexico. On the latter date there were 39 Esperanto societies in thirty-nine American towns. In Europe 63 new societies were formed, the principal new additions being 22 in Germany and 5 in Italy. The total number of European societies was 295. The total recorded number of Esperanto societies throughout the world on November 5th was 1,130. The total number of Esperanto magazines was 69. Esperanto has received official recognition in various countries. Thus in Austria-Hungary the Minister for War has given permission to officers and military officials to join the Esperanto Union in Vienna. In France the Departmental Council of the Seine has voted a subvention to the Esperanto Group at Charenton, which also received two further subventions from the municipalities of Charenton and Saint-Maurice. In Cochinchina the Colonial Council has voted a subvention of £20 to the Esperantist Group at Saigon. The use of Esperanto in telegrams was sanctioned in Russia in 1904.

Medical News.

THE late Professor Sacharjin has left two millions of roubles for the erection of a hospital in Moscow.

THE annual dinner of the West London Medico-Chirurgical Society will take place at the Great Central Hotel, Marylebone, on Friday, February 12th.

A NUMBER of medical officers of the Turkish army have been sent by the Ottoman Government to go through courses of study in German and French universities.

A PAPER on the purification of water by ozone and other chemical substances will be read by Dr. S. Rideal at a meeting of the Royal Sanitary Institute, at the Parkes Museum, on Wednesday next at 8 p.m.

PROFESSOR ROBERT KOCH has been elected a President of the German Central Committee for the Prevention of Tuberculosis, in the room of its founder, the late Herr Friedrich Althoff, Ministerial Director of the Prussian Education Office.

THE usual course of lectures and demonstrations at the Hospital for Sick Children, Great Ormond Street, W.C., will commence on Thursday next, when Mr. Arbuthnot Lane will give a lecture on fractures in children, at 4 p.m. The lectures are free to qualified medical practitioners.

THE second lecture of the Hunterian Society is to be delivered by Mr. Bland-Sutton at the London Institution, Finsbury Circus, next Wednesday evening. He will deal with thrombosis and embolism after operations on the female pelvic organs. The lecture is free to all members of the medical profession.

THE second international course of legal psychology and psychiatry at the University of Giessen will be held from April 13th to 18th, 1909, under the direction of Professor Sommer, with the co-operation of Professors Mittermaier and Dannemann of Giessen and Professor Aschaffenburg of Cologne. Further information can be obtained from Dr. Sommer, Professor of Psychiatry, University of Giessen.

A PROVINCIAL sessional meeting of the Royal Sanitary Institute will be held at Manchester on Friday, January 22nd, when, at 2.30 p.m., a visit will be paid to the new Manchester Royal Infirmary. At 7 p.m. a discussion on the infirmary from the hygienic, sanitary, and aesthetic points of view will be opened by the architects, Mr. Edwin T. Hall and Mr. John Brooke.

THE Clinical Society of Newcastle-on-Tyne will entertain Sir Thomas Oliver at its annual dinner on January 14th, in order to congratulate him upon the honour of knighthood recently conferred upon him. On the afternoon of the same day Sir Thomas Oliver will give an address to the

society on the use of caissons in bridge building, with remarks upon the physiology and pathology of compressed-air illness.

THE constitution of the King Edward VII's Hospital for Officers, Grosvenor Gardens, S.W., has been altered. There is no longer an honorary medical staff, as the appointments were for five years only. Patients may now be treated by any member of the surgical staff of a London hospital, and, prior to admission, an officer should select his surgeon and arrange with him as to fees. The hospital is for surgical cases only, and will be maintained as a free nursing home.

THE German Urological Society will hold its second congress at Berlin, April 18th to 22nd, 1909. Among the subjects to be discussed are urology and gynaecology, suppurative non-tuberculous affections of the kidneys, and tumours of the bladder. An exhibition will be held in connexion with the congress. All communications relative to the congress should be addressed to Sanitätsrat Dr. Vossido, Victoriastrasse 19, Berlin, W.

DR. JAMES KERR, Chief Medical Officer of the London Education Committee, will deliver the first of a course of lectures and demonstrations on the medical inspection of school children at the rooms of the Society of Medical Officers of Health, 1, Upper Montague Street, London, W.C., on Monday next, when the chair will be taken by Dr. Charles Newman at 3 p.m. The lecture will deal with the general principles of medical inspection and with annual reports. An exhibition of appliances and material relating to medical inspection is being organized. Full particulars can be obtained from the secretary of the society at the address mentioned.

THE Lord Chancellor has placed on the Commission of the Peace for the County of London the name of Surgeon-General Sir Charles Cuffe, K.C.B., Army Medical Staff (retired). Sir Charles Cuffe is a member of the Naval and Military Committee of the British Medical Association, and Vice-Chairman of Council of the Kensington Division, Metropolitan Counties Branch. President for 1908-9 of the Irish Medical Schools' and Graduates' Association. He serves on various boards of management of industrial and other certified Poor-law schools, is a Poor-law guardian of Kensington, and a member of the Council of the Royal Borough of Kensington, which he has represented since November last on the Joint Subcommittee for Kensington and Westminster of the London County Council for investigating the claims under the Old Age Pensions Act, 1908.

MR. C. F. P. CAVE has reported to the Royal Meteorological Society the results of a number of experiments with kites and balloons arranged by the International Commission for Scientific Aeronautics, with the object of determining the state of the atmosphere as regards temperature and wind velocity at great elevations. The average height reached by the balloons was 10.2 miles, the greatest 14.2 miles. Some of the resulting thermographs showed considerable differences between the up and down tracings, and this was deemed to indicate that fairly rapid fluctuations of temperature may occur in the upper air. Other tentative conclusions put forward were that after a certain height is reached there is no longer a fall of temperature with increase of height. Above a certain altitude there may even be an increase of temperature which cannot be explained by solar radiation, for some of the balloons recording such rise reached their highest point after sunset. At the lower limit of the isothermal layer it would appear that there is a well-marked diminution of wind velocity.

THE distribution meeting of the Hospital Saturday Fund for London was held on January 2nd, £25,000 being divided among the various applicants. The ordinary receipts for the year amounted, it was shown, to £22,659, an increase of some £1,600 as compared with the previous twelve months. It was reported that during the year 1,556 letters of recommendation for convalescent homes had been issued, rather more than two-thirds of these being for admission on the part-payment system. During the previous three months 61 patients had been admitted to the beds endowed by the Fund in various consumption hospitals and sanatoriums, while 41 patients had been admitted to the Brompton Consumption Hospital on the recommendation of the Fund during the year. In the surgical appliance department the attendances of patients reached 8,026, the payments made by them exceeding £1,173. In its report the Distribution Committee drew attention to the fact that the waiting list at various institutions intended for the consumptive continued to be most unfortunately long, and put forward a suggestion that the Fund should endow a greater number of beds in those on which the demands were greatest.

British Medical Journal.

SATURDAY, JANUARY 9TH, 1909.

MEDICAL INSPECTION AND SCHOOL CLINICS.

THE British constitution, of which we are all so proud, exists, it is said, only in the mind of the Speaker of the House of Commons, who, whenever the machinery begins to creak too audibly, evolves from his inner consciousness a new clause. Certain it is that as a people we have no love for a complete, logical, comprehensive scheme. The Abbé Siéyès, that ingenious framer of complete, logical constitutions, would not have had a day's shrift with us. We have taken to heart the injunction to do that which our hand findeth to do to-day and to leave to-morrow to look after itself. We sympathize with Sir Boyle Roche's rhetorical question, What has posterity done for us that we should do so much for it? We do not cross any bridges until we come to them, but sometimes the bridge proves to be round the next corner, and with much screeching of brakes and blowing of horns we are pulled up to see whether it is wide enough and strong enough for our car to pass. These, perhaps trivial, reflections are inspired by the present attitude of the public, or at least of the ratepayers, towards the great question of the health of school children.

The public conscience demanded medical inspection of school children, and Parliament, in making that measure compulsory, added a permission to local authorities, to make arrangements, with the sanction of the Board of Education, for attending to the health and physical condition of children educated in public elementary schools. It provided, also, that the local education authority might encourage and assist the establishment or continuance of voluntary agencies and associate with itself representatives of voluntary associations for the purpose. Medical inspection, as was expected, has disclosed the fact that a large percentage of children in elementary schools need medical treatment; nobody doubts that it must be provided for them in some way, and the ratepayer is lamenting the possibility—nay, the certainty—that it will cost money, and is seeking a compromise.

The matter has been brought to a sort of crisis in London by the report of the special committee to the Education Committee, which was published in the JOURNAL of December 26th, 1908, and is further dealt with in an article this week at page 96. The same problem, on a proportionately smaller scale, is confronting other local authorities throughout Great Britain, and it may be well to examine some of its features, taking London as the most recent and, owing to its size, the most striking example.

It seems clear that the medical attendance and treatment required must be given by private practitioners, by existing voluntary hospitals and dispensaries, by provident dispensaries and societies, or under the Poor Law, unless the education authority itself institutes a system of school clinics. The map of London printed in this issue (pp. 100-101) shows in a striking way that the voluntary medical institutions, even if they were prepared to undertake the

task of caring for school children or if it were politic that they should make the attempt, are not so placed topographically as to render success possible. The work will have to be done locally, and ought naturally to fall to the lot of the members of the medical profession practising in each locality. The Annual Representative Meeting last year adopted a resolution to the effect that the services of the profession should not be given gratuitously to patients who are maintained by public funds, and it appears now to be universally recognized that the treatment of school children in school clinics or elsewhere must be paid for, and though this ought to be a truism, yet in these days it is something gained to have the principle clearly admitted.

The general practitioners of London could without doubt do the whole of what has to be done if they were afforded adequate nursing assistance in certain classes of cases—ringworm and sore heads, for example—and with opportunities for reference and consultation in special cases. Certain classes of cases, such as errors of refraction, would be referred for treatment; while the result of consultation would be provision by charitable or municipal action for chronic debility or illness; children suffering from, or suspected of, internal tuberculosis, for example, would be sent to country schools or sanatoriums.

It seems clear either that the general practitioners must do this work, the greater part of which they already do so far as it is done, or that their field of practice must be seriously diminished. The number of children to be examined and treated will undoubtedly be large, and the administrator's difficulties begin when the question of the organization of the work and the remuneration of those who do it are considered. If we leave out of consideration skilled artisans earning high wages, who as a class appear willing to make provident provision for sickness, there would seem to be only two possible ways in which the work 'can be' remunerated—by a great extension of the provident dispensaries and clubs, or by the municipality.

Now it is a fact that the provident principle has made relatively little headway among that very large class of the working population, larger perhaps in London than in any other city in the country, which earns small weekly wages or exists by casual labour. London is a great port and dépôt of merchandise, and the number of men engaged in handling goods and carting them from one place to another is enormous. The labour is unskilled and very badly paid in relation to the cost of housing, which is probably the most reliable standard of comparison. A certain proportion—we believe a large proportion—of this class does make some provident provision for maintenance during illness of the breadwinner, but does not usually go beyond this, and many do not do so much.

It is easy to say that all ought to make provision; but they do not, and it would seem that the medical profession, as a body of practical men, must either ask the State to insist on compulsory providence, or find some other way of providing medical aid to them and their families in sickness.

Mr. Warren, the representative of the Metropolitan Provident Medical Association, in his evidence reproduced at page 97, stated that there were 38 provident dispensaries in London, that there were about 110,000 persons enrolled as provident members of these institutions, and that of this number some 50,000 were children. As there are probably about 700,000 children of school age in London, it is not too much to say that

the provident dispensary system has, so far, only touched the fringe of the matter. Mr. Hancock Nunn, who also gave evidence (p. 97), expressed the opinion that the juvenile benefit societies could be so extended as to meet the difficulty, but neither of these gentlemen seems really to have thought the matter out, and both admitted that the provident organizations would have to be subsidized by the London County Council if they undertook the work. From whatever side we approach the question, therefore, it seems clear that State aid in some form must be given.

QUINCE'S BUILDING.

A great deal is expected from the report of the Royal Commission on the Poor Laws, but a Royal Commission cannot alter economic conditions: it can only point to means by which their evil consequences may be prevented or diminished. Short of recommending a scheme of universal compulsory sick assurance on the German plan, it is difficult to see what it can propose except an extension of the non-contributory State system of aid in incapacity and old age which has been developing in this country during the present generation. The acceptance of medical relief does not deprive the recipient of civic rights. The Poor-law infirmaries have been converted into well-equipped institutions precisely analogous, except in respect of the medical staff—undoubtedly an important exception from certain points of view—to the great hospitals of Paris or Berlin. Old age pensions have superseded the instruction of the Local Government Board's circular of 1900, "that aged deserving persons should not be urged to enter the workhouse at all unless there is some cause which renders such a course necessary, such as infirmity of mind or body, the absence of home accommodation or of a suitable person to care for them, or some similar cause, but that they should be relieved by having adequate outdoor relief granted to them"; and lastly, as a matter of fact, more than half the total expenditure made out of the poor rates is for purposes altogether unrelated to the relief of the poor: so that if the Poor-law system were abolished to-morrow, the work it does, or by far the greater part of it, would have to be continued under another name.

We have in this country drifted with the tide, not knowing exactly whither we were going, while the German mail boat has gone by us on the steady course laid down by the great pilot Bismarck. But the experience of the medical profession in Germany should be quite sufficient to teach the profession in this country—if indeed it still needs the lesson—that the State will not go out of its way to deal generously with doctors. It has this, at least, in common with Providence, that it is disposed to help those who help themselves, and in the readjustments which are being made, and the many others which will without question have to be made within the next few years, it behoves the medical profession to look after its own interests. But it is essential that the questions should be approached in a statesmanlike spirit, and with a disposition to adapt the medical system to changing social and economic conditions. The State is committed to the policy of providing medical relief, not only for the legal pauper and for the small wage-earning and casual labour classes, but also to giving or procuring proper care for sick or defective children of school age. We cannot see any escape from the conclusion of the Special Subcommittee that, though existing provision of private and hospital practice, to which

we may add the Poor-law infirmaries, sufficiently meets the requirements in the case of children requiring operative and in-patient treatment, other provision must be made for medical treatment of the very large mass of cases of physical deficiencies, including defects of the eyes, ears, and teeth, which are being disclosed by medical inspection.

The State, as has been said, is committed to the principle that the children are to be cared for; it will have to find the money necessary to fill up the large gaps left by the voluntary system, and though local authorities are shying at the suggestion that an additional charge must be put on the rates, it is morally certain that the money will be forthcoming.

A report by the Medico-Political Committee of the British Medical Association on certain points connected with the medical inspection of school children, and the treatment of those found to be defective, has recently been referred to the Divisions, with a request for an expression of opinion on a series of questions dealing with both aspects of the subject. One of these questions asks for the view of the Division as to the distribution and method of selection of the staff of school clinics should their establishment be proposed, and the mode and rate of remuneration; another asks for suggestions as to the methods of ensuring that parents who can afford to pay for the treatment of their children when found to be defective as the result of medical inspection should be compelled to do so.

SPIRITUAL HEALING.

In the JOURNAL of April 30th, 1907, p. 951, and again in that of November 21st, 1908, p. 1579, we discussed an interesting movement for "the moral treatment of nervous disorders" which was recently started in America, and may, for convenience, be referred to by the title of the Emmanuel treatment, from the name of the church in Boston where it seems to have had its origin. In a further article, entitled *Ministries of Healing*, which appeared in our issue of November 28th, 1908, p. 1634, we gave an account of debates on spiritual healing at the Pan-Anglican Congress and the Lambeth Conference held last summer. It was further stated that an association, called the Church and Medical Union, had been formed, with the object of promoting the co-operation of the Church and the medical profession in the healing of the sick. The principles on which the union professes to carry on its work are those embodied in the report of the Lambeth Committee, which were summarized in that article. Our readers have therefore had ample opportunities of learning the objects of the movement and the methods by which they are to be attained. The secretary of the union is Mr. Geoffrey Rhodes, and its headquarters are at Dryden House, 43, Gerrard Street, London, W. The objects of the union are stated to be (1) to establish head quarters in London where books and literature may be consulted, and where persons may come for advice and information; (2) to canvass the clergy and medical men generally all over Great Britain with a view to obtaining their co-operation; (3) by means of literature, lectures, and meetings, to obtain support for the union and the objects for which it has been formed; (4) to recommend courses of reading, as samples of which may be mentioned *Mental Healing*, by the Bishop of Bloemfontein; *Christian Science* and *"Spiritual Healing"*, by Prebendary Yorke Fausset, both published by the Society for the Propagation of Christian Know-

ledge; and *Religion and Medicine*, by Worcester, McComb, and Coriat (reviewed in the JOURNAL of November 21st, 1908), and *The Healing Ministry of the Church*, by the Rev. Dr. S. McComb; these two works are published in this country by Messrs. Kegan Paul, Trench, Trubner and Co., Limited, whose offices, by a convenient coincidence, are at the same address as the head quarters of the Church and Medical Union. A short time ago interviews with Mr. Rhodes appeared in various newspapers. To a representative of the *Daily Mail* he is reported to have said:

"Men and women will be in attendance at our head quarters to interview the patients, who will be asked to give a certificate from the doctor who is attending the case. Then we will arrange for the patient to be seen by a clergyman—if possible by his parish priest. The clergyman of the future will have to study psychology, and it is our intention to have lectures and classes on mental therapeutics, where the clergy will learn how they can help those who need their aid."

How they are to apply their knowledge of "mental therapeutics" when acquired we are not told; nor do we know how far the union has advanced in the realization of its objects. We have seen none of the literature which the union is to make it its business to issue; nor have we seen any accounts of lectures and meetings in its support. What is still more important, we have seen no report of cases treated or of the results obtained. We confess we feel some curiosity as to the exact position of the union, and we should like to know how many members it has so far enrolled. It would also be interesting to know something definite about Mr. Rhodes's special qualifications for the task—useful in itself, but needing for its successful performance, in addition to enthusiasm, wide knowledge and infinite tact—he has undertaken. Till satisfactory information on these points is forthcoming, the medical profession, however much individual members thereof may sympathize with its objects, will be well advised not to give any active support to the union.

Another professor of spiritual healing, who took part in a meeting held at Sion College on November 16th, with the object of promoting the formation of a Central Church Council in the diocese of London for the consideration of questions connected with healing by spiritual means, is Mr. James Moore Hickson, described as of the Society of Emmanuel. He is reported to have said on that occasion that the society was formed more than three years before with the object of reviving in the Church the gift of healing. The members of the society, he said, acted through prayers, the laying on of hands, and, when requested by a patient, anointing, which was performed by a priest. He added that they were in sympathy with all kinds of healing, which they considered to be a gift of God, but they wished for a more spiritual atmosphere round a patient. The Emmanuel Society, it is to be inferred, exists to supply this want. From a little magazine¹ published by Mr. Hickson we learn that he is the President, Lady Mosley the Honorary Treasurer, and the Rev. Charles Mylne the Chaplain of the society. The following are stated to be its objects: "(1) To develop the Divine gifts left to His Church by the Master, especially the gift of healing by prayer and laying on of hands, with the object of using these divine gifts, not only for the healing of the body, but

"as a means of drawing the souls of men nearer to God. (2) To further this purpose by opening a hostel, especially for poor gentlefolks, a class who are beyond the reach of ordinary help where their cases may be diagnosed by duly qualified medical men, and where a band of healers may develop and use their gifts to further the work. (3) To form a strong wall of defence against the powers of evil, by mutual united intercession, and by common reception of the Holy Communion on the Second Sunday in the month. (4) To safeguard the central doctrine of the Incarnation, all regular members should acknowledge the divinity of our Lord *although the operations of the Society should be freely used for all in need of them.*" From a paper by the Rev. George P. Trevelyan published in the first number we learn that the society does not concern itself about every kind of spiritual healing: "That term is used to include healing by mental suggestion and also healing by prayer, apart from a special gift of healing in the person who prays for the sufferer." In a paper which appears in the third number the Right Rev. Bishop Mylne, D.D., says, "In the latest up-to-date book on cancer, which is in the hands of the most scientific men of to-day, there is a case quoted which is, I have no doubt, correctly said to be a unique one of abortive cancer. The case is fully described from a medical point of view—how a patient, stricken unquestionably with cancer, was found to have in place of the tumour, located and verified by several experts, something which could only be called an abortive cancer, the like of which was never heard of before. I happen to know the whole history of the case from the brother of the patient, himself a medical man. It was this: The patient had been suffering from a serious affection of the throat. He went to one specialist after another. Three eminent men told him without hesitation that he was suffering from a cancer growing on the vocal cords, and that nothing but their total excision would save his life. He was a hard-working priest of our church, and of course the operation meant that he would never utter a word again. However, his life had to be saved. The doctors came; the throat was laid open; the operator had the knife in his hand to excise the vocal cords. He stopped dead. Instead of applying the blade of the knife, he took hold, between his thumb and the handle, of all that he found there, and peeled it off like the skin of a fruit. Between the diagnosis and the operation the patient had been anointed with oil in the name of the Lord. That is one of not a few cases which some of us know about, but it is by far the best defined one I know of, and one that is actually celebrated in medical circles: not, of course, being quoted as an instance of what may be done by anointing, but as a case unique in surgical experience." We should be glad to have fuller particulars of this unique case, and for that purpose we respectfully invite Bishop Mylne to furnish us with the name of the "latest up-to-date book on cancer" from which he quotes.

The variety of cases with which the Society of Emmanuel deals may be gathered from the list of patients for whom prayers are asked. The diseases include blindness, "internal weakness" (which seems to be so common among members of the society that we are tempted to suspect that the seat of the affection is the brain), internal growths, consumption, and deafness. There are several cases of insomnia, and we are willing to believe that a perusal of *The Healer*

¹ *Daily Mail*, November 21st, 1908. ² *The Healer*. Printed for the Publisher, J. M. Hickson, Esq., 24, Tavistock Square, W., by Roberts and Lee, Limited, Bedford Street, London, S.E.

would be a valuable remedy for that ailment. Reports of cases of cure of "cancer in bowel," rupture, locomotor ataxy, and colitis are given in the style adopted by the advertisers of quack medicines, but without any clue by which the patient can be traced.

In another number there is a report of a conference of spiritual healers held at Pinner in July last, and it is stated that among those present were the Bishop of Dorking, the Duchess of Bedford, Lord Radstock, Lord Sandwich, and Miss Reed, M.D. We do not call in question the good faith of any of these persons, but we confess we should like to know something more about Mr. James Moore Hickson, who appears to be the moving spirit of the Society of Emmanuel. In *Truth* of November 25th, he is described as a gentleman who probably at one time devoted his energies to massage. Now it would appear he heals by prayer. We are quite open to conviction in respect of the efficacy of his treatment if he will furnish facts on which a judgement can be founded. The art of healing, whether by carnal or by spiritual means, is full of fallacies, and it is a pity that, like so many healers, Mr. Hickson gives no particulars by which the nature of the disease and the genuineness of the cure can be established. Nor is it stated whether the "healing" is done gratuitously.

We have seen that a Miss Reed, M.D., was present at the conference to which reference has just been made. This lady, whose full name is Eleanor M. Reed, and who describes herself somewhat vaguely as "M.D. (U.S.A.)," also took part in the proceedings of the Pan-Anglican Congress, where she oracularly declared that "the real principle of healing was 'intellectual and physical co-operation with the vital powers within the organism itself.'" She added, as if she were announcing a new discovery, that "they needed to realize that the body responded to emotional states, whether there was truth or error behind the emotions; and, given the mental state, they were sure to get the physical results." Although she criticized Christian Science, she said its theories and practices tended "to give poise to the controlling power of mind." We do not gather very clearly what Miss Reed's own method of treatment is, unless it is to be found in the following eloquent but rather cryptic sentence: "Are we not so busy in criticizing the Church that we have no time to study the beauty of the Christian mind, the fruit of her labour—a mind, hallowed by adoration, illumined by faith, empowered by grace, sweetened by divine love —such is the realm in which she bids us look for the 'armour of our physical salvation?'"

We do not know how far these various representatives of spiritual healing agree with each other; we think it not unlikely that they hate each other with the fervour which is generally proportionate to the intensity of the theological belief. If all or any of them can show that they have discovered a new force, or a new method of applying one already known, to the cure of disease, rational medicine will welcome a new weapon. As we have often said, the wise physician understands the action of the mind or the spirit on the body, and uses it for the benefit of his patient. A man who firmly believes in his doctor's skill, or in the efficacy of the treatment to which he is subjected, is in the best possible condition for the operation of curative forces. On the other hand, a patient who believes that nothing can cure him helps to seal his own doom. Avicenna well said, *ipsa interdum prodesse fiduciam in medicum quam ipsam medicinam*. The "lady of the highest rank," who is reported to have said that she would

rather die under the care of Sir Henry Hallford than recover under that of any other physician, must have been a living tribute to his skill.

The fact cannot be too much insisted upon that there is nothing in the least new about faith healing. It is as old as medicine and religion, which in the beginning were one, as they still are among many savage tribes. Faith can move mountains, and it matters little on what it is based or how it is excited. As John Hunter has told us, the touch of a dead man's hand has charmed away a tumour. But there are limits to its action, and while willing to accept faith as an adjuvant, no one who knows anything about disease will admit that by itself it can heal any but ailments the origin of which lies hid in the unknown recesses of the nervous system. By all means let us know the full power of the spirit over the body. Only let us have facts that can be fairly and fully tested. A scientifically trained doctor takes nothing on trust, and there can be no useful co-operation between medicine and spiritual healing unless the facts of each case are fully disclosed. That is the point where science and faith part company; the former is as importunate as Arthur Clennam at the Circumlocution Office, and the wonder workers are as painfully surprised at this as the youthful Barnacle was at the persistence of "the fella that wanted to 'know, you know.'"

PURIN-FREE DIETARIES.

It is generally admitted that the metabolism of purin bodies is a complex process, and that our knowledge of it is far from complete. We know, however, that the purins of animal tissues are derived from the metabolism of cell substances, and are constantly being excreted by the usual paths. When a minimal quantity of these substances is taken in the food, it is permissible to infer that the amount of purin excreted represents the extent of the cell metabolism of the body tissues. As a matter of fact, recent investigations tend to show, other things being equal, that the largest amount of purin is excreted when the standard of health and activity is at its highest, but it has to be remembered that the relation of the amount of excreted purin to that actually formed by the cells of the body is still unknown. The assumption that the purins produced by the cells undergo the same metabolic changes as those purins which are introduced into the body with the food has become current—but after all it is only an assumption. There is much more work to be done before dogmatic statements may be accepted upon this aspect of the subject.

From the investigations of Leathes and his co-workers it appears that there is a tide in the excretion of purins (uric acid and purin bases) which is at flood in the early hours of the day, and ebbs towards the night, while the output of urea is lowest in the early hours of the day and highest after the last meal. The purin output, therefore, is not related to the amount which is being dealt with at the moment, and can only be ascribed to some functional activity connected with the general metabolism. The variations in this activity probably account for the variations in the purin output of the healthy individual when taking a purin-free diet. That these apparent irregularities of output are not due to retention of uric acid and purin bases has now been definitely shown, and it is generally accepted that when the purins are extruded from the cells they are rapidly removed from the body.

When we consider the metabolism of food purins we find that a fraction of the ingested purins rapidly appears in the urine; the remainder cannot be accounted for in detail. Certain foods yield more, others less, urinary purin. The fractional output varies in different individuals, and in the same individual under different conditions. Much has been made of the toxicity of the food purins, and there is some experimental evidence to support the contention, but it is probable that under ordinary conditions uric acid and the purin bases are almost non-toxic. It has to be admitted, however, that it is quite possible for purin bodies to combine with imperfect metabolites so as to form an irritant compound.

In local or general disease the nucleus of the cell bears the chief brunt of the action of bacterial or chemical poisons, and we naturally expect to find that certain infective or toxic conditions are associated with an increased functional activity of nuclear tissues, and, consequently, with an augmented purin output. What we so expect we certainly find, and it is also clear that this output is quite apart from an increased intake, that it is not due to a washing out of the previously retained purin, and that, as a rule, it reflects rather than affects the progress of the disease.

There are, however, a few individuals whose cells do not tolerate well an excess of purins in the tissue fluids—either of exogenous or endogenous origin—and this intolerance is manifested by certain functional disturbances. In these cases the temporary withdrawal of purin material is followed by a cessation of the symptoms. This diminution of purin intake is complicated by the fact that it is almost invariably associated with a decreased amount of protein, and consequently with a decrease of any unknown thermostable substances present in the food which may possess irritant properties. On a purin-free diet, therefore, the patient absorbs less nutriment, and as such patients are generally of the hypersensitive type, the idea of eating a small amount of food may become a "fetish," and so tend permanently to lower the resistance of the tissues to toxins and cancer-cell growths. Among vegetarians a "uric acid free diet" was once advocated, but it is now recognized that such a diet contains too little protein, and an adequate intake of nitrogenous material is rightly insisted upon.

Assuming, therefore, that a strictly purin-free diet is a reduced diet and only a temporary necessity, we may proceed to construct suitable dietaries, and also to detail the foods which may be permitted during a transition period which may suitably precede the resumption of a low average protein dietary.

For experiments in metabolism it is necessary to determine the exact amount of calories and nitrogen yielded by the food consumed. In everyday life, however, this is not practicable. While the patient will readily learn what may or may not be eaten, he rarely carries out instructions as to quantities. The physician, therefore, has to control the intake by keeping a record of the body weight, and by examination of the urea or total nitrogen, acetone, etc., at regular intervals. The urine must also be repeatedly tested for sugars, as there are certain families whose members exhibit glycosuria when the carbohydrates and vegetable proteins are increased.

Speaking generally, the foods which contain little or no protein should be the first to be discarded and the last to be resumed. Unfortunately, however, these are the foods which provide the pleasurable

and stimulating effects of eating. It is thus an advantage not to change the dietary too abruptly, and for a fortnight or so the patient should be advised to restrict slightly the amount of food taken and to eat fish or meat once a day. With regard to drink, not more than two small cups of tea or coffee or chocolate should be taken daily. Soups, beer, ale, and porter ought to be avoided, but claret, Burgundy, hock, whisky, or gin may be substituted when there are no conscientious objections to them. For total abstainers quassia or other bitters are useful, but fermented temperance drinks are not well tolerated. Condiments may be permitted unless renal conditions contraindicate their use.

After this probationary period the "purin-free" diet may be prescribed. The term "purin-free" is, however, a misnomer. A precisely "purin-free" diet would be composed of milk, eggs, white bread, cheese, butter, and a few vegetables; but when the milk contains many cells, as it often does, and the eggs are not absolutely fresh, as they often are not, their purin content comes within the range of our present chemical methods. Because a food is poor in purin we have assumed in the past—and probably we have erred in doing so—that it could not disturb the general purin metabolism; we have yet to learn whether this is so or not. We are really dealing, therefore, with a dietary which is designedly poor in purin. For this purpose the following foods are at our disposal: Milk—fresh, soured, buttermilk, or whey; eggs—boiled, poached, scrambled, or raw; white (not brown) bread and butter; macaroni and cheese, rice, tapioca, semolina, and vermicelli. Suet may be used for puddings of all kinds, such as currant or jam roll, treacle, apple dumpling, etc. Pastries, pancakes, jellies, and the usual tea cakes are also available. All vegetables, except the pulses (peas, beans, and lentils) are poor in purin. Practically all fruits may be permitted. As to drinks, tea, coffee, or cocoa are excluded, and hot water, claret, or burgundy, mineral waters, or hot milk may be substituted. Beer and porter should be discontinued, and alcohol diminished as far as the usual habits make possible. Condiments are generally craved for, and there is nothing to be gained by withholding them unless they are otherwise contraindicated.

After a month or so of this diet a return to the usual form of human food should be attempted. Brown bread, oatmeal, wholemeal, beans, peas, nuts, asparagus, or mushrooms may be gradually added. If it is desired to employ vegetable protein only, then these latter foods should play a large part in the dietary. When animal protein is preferred, sweetbread should be the first kind of meat allowed, since the purins contained in sweetbread are "bound purins," and are badly absorbed, the greater proportion passing out in the faeces. Later, codfish, sole, plaice, mutton, chicken may be permitted, salmon, halibut, and beef and pork being reserved for later periods. When meats are again taken they should be stewed, not roasted, and milk sauce substituted for the meat gravies.

Even when a return to full diet is made it is well to restrict tea, coffee, and cocoa, and to limit soups. With regard to extracts, there is little to choose between any of the obtainable preparations. The purins of yeast extracts are less well absorbed than those of meat extracts, and theoretically are less harmful, but the differences are exceedingly slight.

It will be evident that the prescription of a diet poor in purin calls for careful observation on the part of

The physician. The danger signals of starvation, of glycosuria, and of mental bias, should always have attention, and a return to the average dietary should be the object aimed at. Much information may be gained by the daily determination of the total purin output by clinical methods, but when this is impossible the weight and general condition of the patient may afford useful information. A probable result of the treatment will be a diminution of the amount of protein consumed, but the quantity of food necessary for the maintenance of life and for the provision of latent resistance to disease varies with every individual, and with the same individual at different periods of life, so that it is well to realize that rigid prescriptions and rules as to food are but rarely applicable, and that the percentage of good results from the use of a diet poor in purin depends largely upon the sagacity of the physician, and even then is not so high as the enthusiast suggests.

THE HONG KONG AND CHINA BRANCH.

IN the SUPPLEMENT of this week we publish the official report of the annual meeting of the Hong Kong and China Branch. The report of the honorary secretary and treasurer, Dr. J. Herbert Sanders, shows that the Branch is in a flourishing condition. It has now 130 members, and extends throughout districts right into the far western portion of China. It will be noted that a library with reading room has been established for the use both of members resident in Hong Kong and of those who may be passing through the town: it will also be available for naval surgeons on the station. The library, which contains the latest standard books of reference, cannot fail to be of the greatest service to members. Men practising in distant colonies have many opportunities of adding to knowledge, but they are often handicapped by the want of books of reference. We therefore congratulate the Hong Kong and China Branch on the manner in which the members have chosen to use the grant made to the Branch by the patent Association. The greatest credit is due to the officers, and especially to Dr. Sanders, for the energy they have brought to the discharge of their duties.

THE INDIAN HONOURS LIST.

THE New Year Indian Honours List has been issued from the India Office. A special feature of the Royal Message is the increase in the number of appointments to the Order of the Indian Empire and the Order of the Star of India, in commemoration of the fiftieth anniversary of the assumption of the government of India by the British Sovereign. An increase in the pay of Indian officers and men is also announced. The honours awarded are bestowed chiefly upon native princes and officials, and upon members of the Indian Civil Service; but, in addition, the following officers of the Indian Medical Service are honoured: Surgeon-General Gerald Bomford, C.B.E., M.D., Director-General, I.M.S., is made a Knight Commander of the Order of the Indian Empire; Lieutenant-Colonel John Tasman Waddell Leslie, M.B., I.M.S., Sanitary Commissioner with the Government of India, and Major Walter Hood Orr, I.M.S., Civil Surgeon of the Bahraich District, United Provinces, are made Companions of the Order of the Indian Empire; and Captain Eugene John O'Meara, I.M.S., Civil Surgeon of Mirzapur, United Provinces, receives the Kaiser-i-Hind medal for public service in India.

PRAYER AS AN INSTRUMENT OF MURDER.

HEALING by prayer—or, at any rate, talk about it—is much with us just now. We have also a dim notion that there exists—or did exist, a society for the suppression of vivisection by prayer. Possibly because this has failed, the spiritual weapon is now turned against the vivisector himself. The idea is not altogether new for it is recorded in the life of the late Dr. Anna Kingsford that she used to boast of the vivisectors whom she had done to death by the power of her will. If we remember a right the poor lady had to confess that she had found Pasteur too tough a subject: at any rate her efforts to “remove” him by the spiritual forces she claimed to have at her disposal for some reason or other were not successful. Prayer is now suggested as a lethal weapon to be aimed at vivisectors. There has recently come into our hands a printed document with a covering letter signed “M. Cowan” (without date or address: it would appear that it is being sent to assistants in laboratories. The writer says:—“Some little time ago, in the coffee room of a London hotel, I chanced to hear one of the party at a table close by narrate how he knew a person who was in the habit of praying from time to time for the death of one of our leading vivisectors: he said that always the man indicated had died. I tried to trace the speaker, but, as time had elapsed, did not succeed in doing so: I then thought, as I myself know of the efficiency of prayer, it would be well to try if this were actually so. I thought first of experimenting on Dr. Starling; but it seemed to me unfair to give such a stab in the dark without first letting it be known what was intended. It seemed also almost cruel, without knowing any of the surrounding circumstances, to select at random one from the large number of distinguished scientists on the medical lists. It was, therefore, finally decided to make earnest prayer, giving much thought to the subject, that the Almighty, if the prayer were in accord with His Will, would promptly remove the man most likely to cause future suffering to innocent subjects by his experiments. About a fortnight later, one of our most distinguished medical scientists dropped, and the newspapers were lamenting the loss to science of this vivisector, and the discoveries he was just about to make. It would be interesting to know who was the vivisector here stated to have been prayed to death. We hope Professor Starling feels duly grateful for his escape. Further on M. Cowan propounds a theory of anaesthesia which is as new to us as it probably will be to those antivivisectionists who deny that animals can be, or at any rate are, rendered insensible before experiment. We quote the writer's own words:—“Our Saviour distinctly states: ‘A sparrow falls not on the ground without our Father’; if that be so, then He stands in the laboratory beside the operating trough. Without doubt, He it is who so often gives an insensibility to the agonies endured, which seems unaccountable to the operator. But does He protect the operator and the watching students from the hardening and vitiating effect of constantly participating in cruelty? We are further told that ‘The prayer of the child of God reaches further, is more searching in its effects, than any enactment of the law can be. Not only does it enter the vivisection room, embracing all operations there; it is with the patients in our hospitals, and by the bedside of the poorest sufferer, and it will make its way into the garret or concealed chamber where the student, eager for knowledge and advancement, illegally tortures his helpless victim from day to day.’”

We gather from this that the "child of God" is not above using the weapons of the devil, who is described as the father of lies. How else can odious calumnies which directly spring from the wish to believe evil be accounted for? Ignorance cannot absolve a writer when the means of knowing the truth are within easy reach of all. We will not quote further from a document which may be described as a mixture of cant flavoured with blasphemy. But though the thing is too foolish to influence even the mind of the average anti-vivisectionist, it has a serious side. What can be thought of the motive which leads a person who is virtually anonymous to send such stuff not to vivisectioners, but to laboratory assistants, on the minds of some of whom it is at least conceivable that it might have some effect? Fanaticism is a law unto itself, and to invite the servants in a laboratory to pray for the death of the workers in whose employment they are might possibly be an incentive to crime.

OPSONINS.

AFTER having spent several months in the laboratories of St. Mary's Hospital, learning from Sir Almroth Wright the technique of determining opsonic indices, etc., Dr. G. Wolfsohn returned to the Schöneberg (Augusta-Victoria) Hospital and continued his observations on the diagnostic, prognostic, and therapeutic methods which depend on estimations of the opsonic content of the serum of patients. The opinion which he expresses on the value of the methods is worth considering, especially since his personal studies under Sir Almroth Wright may be taken as a guarantee that he has mastered the technique sufficiently to obviate errors due to want of proper carrying out of details. After briefly describing the technique and the application of the counts, Dr. Wolfsohn proceeds to discuss the doctrine on theoretical grounds. If the doctrine were sound, we should, he holds, possess a numerical measure of the protective arrangements of the organism, an extremely delicate biological diagnostic test and a certain indication for immunizing efforts. Unfortunately, he says, the doctrine including the theoretical basis as well as its practical application, cannot be accepted *in toto*. He leaves the question as to the nature and origin of opsonins unsettled, but he states that much doubt exists whether phagocytosis is tantamount to immunity. Bacteria which have been subjected to that process have been shown to retain their vitality and power of growth; it has been shown that, as far as vital processes are concerned, bacteria behave differently in the organism from the way they behave *in vitro*, and clinical experience has demonstrated that Wright's doctrine does not always tally with actual facts. In illustration of this Dr. Wolfsohn cites the rising of the opsonic index in cases of surgical tuberculosis observed by McIntosh, in which no improvement was taking place. The author further finds that the opsonic index towards the pathogenic bacterium varies in cases in which it also varies towards other pathogenic micro-organisms. In the course of his observations he came across a scarlatina patient whose serum yielded a very high index to typhoid bacilli, and, in accordance with Wright's doctrine, the diagnosis of typhoid fever would have to be made. The same thing was found in several cases of staphylococcal infections and of tuberculosis. This, together with the fact that the raising of the index and clinical improvement do not run parallel, detract from the specific diagnostic value of the opsonic index.

Dr. Wolfsohn further discusses the sources of error in the counting, and states that in spite of considerable experience, on controlling his counts, differences which might amount to 20 per cent. presented themselves. He therefore concludes that Wright's method of determining opsonic indices is not suitable for clinical diagnosis, by reason of its complicated nature and its high experimental error, and that certain diagnoses would be possible only when very large numbers of cells were counted, and the results were very distinct. With regard to the vaccine therapy, Dr. Wolfsohn is inclined to believe that it has a future. He has, however, applied it only in 14 cases, in all of which but one, a case of staphylococcal sepsis in which no effect was produced, the vaccines seemed to do good. With regard to actual objective improvement he expresses himself very guardedly.

ACCIDENT INSURANCE IN GERMANY.

IN the year 1837 the German *Reichsversicherungsmant* determined that every alteration of the intact condition of those portions of limbs which are used in working lessens the capacity for work, and therefore reduces the power of earning. This had especial reference to the hands. In 1904 the decision was modified to the extent that slight injuries to the fingers were not regarded as justifying a permanent compensation, since the individual sooner or later would become accustomed to the altered condition of the hand, and would be able to make full use of it. It would, therefore, not be necessary for the insurance society to prove an objective improvement in order to lessen or stop compensatory payments, provided that it could be shown that the individual could use his hands sufficiently well for the purposes of his work. This matter is discussed by Dr. G. Ledderhose in connexion with a pamphlet which the North German Iron and Steel Works Society has published. In the pamphlet, some 63 cases of finger injuries and 13 cases of eye injury are detailed, with which the *Reichsversicherungsmant* and the Court of Arbitration have dealt. With regard to the interpretation of what is a slight ("geringfügige") injury of a finger, decisions creating a precedent have been given to the effect that the following injuries are included: The loss of the distal phalanx of any one finger, if the scar is satisfactory; the loss of the ungual and second phalanx of the four fingers of the right hand; the loss of the ungual phalanx of two fingers under certain conditions; and the loss of the whole of the ring, middle, or little finger of the left hand. It is believed that use may compensate these losses and that the hands may regain their full capabilities. Ledderhose appeals to medical practitioners to support the decisions. He wishes them, however, clearly to understand that there are limitations within which these decisions hold good. It may be mentioned by the way that the findings of the Court of Arbitration were not acted on. In one case it was decided, however, that compensation need not be made by the insurance societies for slight inconveniences. Ledderhose holds strongly that injuries such as those mentioned, but which leave adherent scars, trophic disturbances, etc., should not be included, and that when the function of the hand is actually limited by the loss on account of the impossibility of using that portion of the hand which was injured, the individual has a claim for permanent compensation. In submitting a claim for a permanent weekly compensation for an injury to the hand, the claimant should have a good sketch of the injured

part and an exact description of the permanent condition of the joints, stumps, skin, etc., laid before the judges. This ought to be done by the medical man called upon to pass an opinion on the case. The final decision will in all cases depend on the presence or absence of such conditions as contracted scars, loss of muscular power in the hand, tremors, atrophy of bones, etc. In presenting this opinion, the medical man should always remember that the laity is incapable of judging whether limitations of function are real or feigned, and it is for him to supply the information that is required. When the question is asked of the medical expert, whether a finger which has been injured will in the course of time, and without change in the objective condition, cause so little inconvenience to the individual as to permit of full use of the hand, Ledderhose considers that no opinion should be expressed as it is never possible to predict complete adjustment to the altered condition with sufficient certainty to justify a confident reply. The whole question illustrates the fact that the German insurance provisions have gradually become evolved from a condition in which the workman derives more benefit than his injuries justified to one in which every contributing factor has to be taken into account in determining whether or not compensation shall be paid. The workmen naturally wish to claim as much as possible, while it is the object of the *Reichsversicherungsgesetz* to settle each claim as fairly as possible. The medical man who is consulted should preserve a strictly neutral attitude.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.¹

THE first part of the *Oxford English Dictionary* for the year 1909 is a treble section, which carries the work from *premisal* to *prophesier*, and contains 4,381 words, including the many *pre*'s and *pro*'s. There are many medical terms, some of them the product of yesterday (for example, *pro-oestrum*), others several centuries old (for example, *probe*). The last-named word (*probe*) is regarded as an adaptation of the late Latin *proba*, a proof, in mediaeval Latin also an examination, being formed on *probare*, to try or test; its chief meaning is the surgical one of "an instrument, commonly of silver, with a blunt end, for exploring the direction and depth of wounds and sinuses." The earliest illustrative quotation is from a book by Hollyband, dated 1580, and reads "Une petite esprouvette, a small instrument where-with surgeons do search wounds, a probe." From its use in surgery *probe* has gained its figurative employment, illustrated by a quotation (of date 1876) from one of Lowell's odes, "We who believe Life's bases rest Beyond the probe of chemic test." *Prodroma*, with its plural *prodromata*, is another interesting medical term; it is, as Sir James Murray points out, an erroneous formation, apparently in imitation of such etymological forms as *carcinoma*, *carcinomata*, and it "possibly originated in a Latin *prodroma*, singular" for Gr. *προδρομή*, a running forward, or in mistaking "the neuter plural *πρόδρομα* for a singular." It is, therefore, more correct etymologically to say the *prodroma* of the disease were so and so than the *prodromata* were so and so, but custom has justified the latter erroneous plural form. There are two

correct singular forms, *prodrome* and *prodromus* (plural *prodromi*); but the former has been little used and the latter is not fully naturalized. All these terms have the same meaning—namely, a premonitory symptom of disease; thus Blancard (in 1693) defined *prodromus* as "a Disease that comes before" a greater, as the straitness of the Breast predicts a "consumption." *Prognosis*, from the Greek *πρόγνωσις*, a recognizing beforehand or foreknowledge, means "a forecast of the probable course and termination of a case of disease; also, the action or art of making such a forecast"; and Sir James Murray has found for his readers the following self-sure and egotistical pronouncement in the *Medical Journal* of 1805: "I had arrived to that certainty of prognosis, that I could have insured the life of an individual by the treatment I recommended, and his death by any other." Methinks, the gentleman doth profess too much! There is a group of allied words which are associated with *prognosis* in the Dictionary—namely, *prognose*, *prognostic*, *prognosticable*, *prognostical*, *prognostically*, *prognosticant*, *prognosticate*, *prognostication*, *prognosticator*, *prognosticatory*, *prognosticon*, *prognosticous*, and *prognostify*. *Proleptic* is a less known word: it is applied to "a periodical disease, of which the paroxysm recurs each time at an earlier hour," and a quotation explains it thus: "So that if the Ague come to-day at four of the Clock, then to-morrow one hour sooner, and so on"; the Greek word from which *prolepsis* comes is *προλαμβάνειν*, to anticipate. We have referred above to the interesting word *probe*; but this part of the Dictionary also contains the synonymous term *provet* (that is, *provet*), from the French *éprouvette* and *éprouver*, to search out; a sixteenth century quotation speaks of the "provet or soundinge irone" as being used to "sounde the depth of the fistle." Among medical terms which have taken on a more specialized meaning in modern times is *prepotency*; it is defined as "the propotent power of a parent organism to transmit special characteristics to offspring," and *prepotent* itself means "having a greater power of transmitting hereditary features or qualities." The earlier meaning of the word was simply predominant or pre-eminent in power, and as such it was employed by Sir Thomas Browne and many others, until Charles Darwin in 1859 gave it its more restricted signification. Other interesting medical terms are *prenatal*, *prepollax*, *prepuce*, *presbyopia*, *prescription*, *presentation* (in its obstetrical use), *presphenoid*, *preastolic*, *priapism*, *primipara*, and *pronation*; but from the examples referred to above the reader will at once see that Sir James Murray's big undertaking fully maintains its high reputation for scholarship and interest.

DEATH OF DR. ARGYLL ROBERTSON.

THE announcement of the death at Gondal, in India, of Dr. Argyll Robertson will be received with general regret throughout the medical profession, to which his name was so well known, and with feelings of deep sorrow by those who had the privilege of his personal acquaintance. Dr. Argyll Robertson, who was in his seventy-second year, settled in Jersey when he left Edinburgh; but though he had retired from practice he retained his interest in ophthalmology, and attended the Section of Ophthalmology at the annual meeting of the British Medical Association at Sheffield last July. He started for India with the daughter and son-in-law of the Thakur of Gondal so recently as November 30th. We propose to publish some account of his life and work in our next issue.

¹ A New English Dictionary on Historical Principles. Edited by Sir James A. H. Murray. Vol. vii. *Premisal*—*Prophesier*. Oxford: at the Clarendon Press. London, Edinburgh, Glasgow, New York, Toronto, and Melbourne: Henry Frowde. Treble section. January 1st, 1909. (Price 7s. 6d.)

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND SALFORD.

THE MIDWIVES ACT.

GREAT satisfaction has been expressed in Manchester, and still more in Salford, at the announcement that the Lord President of the Privy Council has appointed a departmental committee to consider the working of the Midwives Act. Manchester is, perhaps, more favoured than most parts of the country, seeing that the Manchester Midwives Supervising Committee has for two years carried out in a satisfactory way a scheme of providing medical assistance to patients whose weekly income is below a fixed amount. If evidence were needed of the value of the work accomplished by the Joint Committee of the Manchester and Salford Divisions of the British Medical Association, it would only be necessary to call to mind the fact that it was very largely due to the energetic action of this committee that the Midwives Supervising Committee was induced two years ago to initiate the scheme. The cost to the corporation has been very small, in fact insignificant, compared with the benefit that must have been derived by parturient women, who can now rely on getting medical aid, whatever their position in life may be, whenever a midwife considers such aid necessary.

Exactly the opposite state of affairs, however, exists in the neighbouring borough of Salford. Here the corporation has refused to make any provision for medical assistance in confinement cases, while the board of guardians, not content with offering a scheme which is altogether unsatisfactory to the medical profession, has actually without protest allowed individual guardians to cast unfounded aspersions on members of the deputation that represented both the Medical Guild and the Salford Division of the British Medical Association. The Joint Committee of the Manchester and Salford Divisions is so thoroughly convinced of the lamentable failure of the Act in Salford that it has offered to send several witnesses to give evidence before the committee; it has been informed by the secretary that the departmental committee at its first meeting on December 18th, 1908, resolved "to commence by hearing witnesses on behalf of the central organizations representing the principal interests concerned, and would defer to a later stage the consideration of any applications from individuals or from local associations or Branches to tender evidence." The Joint Committee of the Divisions feel strongly that the committee ought to be fully informed as to the respect in which the Manchester scheme has proved satisfactory, and, on the other hand, how completely the Salford guardians have demonstrated the possibility of making the Midwives Act in certain directions a failure.

TREATMENT OF PHTHISIS IN WORKHOUSES.

At a conference of representatives of Poor-law unions of Lancashire and Cheshire held in Manchester about forty out of forty-four unions were represented. The conference was called to consider the best means to provide special treatment for phthisical cases by combinations of unions or otherwise. It was stated that the three unions of Liverpool had combined to erect a hospital of 54 beds for consumptives. The results, so far as the patients were concerned, had not been satisfactory. There had been a long list of deaths, and after six months' treatment in the hospital most of the patients, on returning to their home surroundings, relapsed into their former state. The weekly cost of each patient at the hospital had been about £3, and it was asserted that, considering the results, this was a serious waste of public money. Several speakers pointed out that the spread of the disease was only to be prevented by the education of the people, in taking of proper precautions, and by the provision of isolation hospitals by boards of guardians. A representative from Rochdale said that during the last nine years 443 cases of consumption had been treated at Rochdale workhouse, and of this number 138 had died in the infirmary. The experience of Bolton was said to be that of every 15 cases sent into sanatoriums 5 came back to

die, and 10 were not cured. Mr. A. B. Lowry, Local Government Board Inspector for the North-Western district, stated that in some cases the Local Government Board had refused to sanction proposed combinations of unions pending the report of the Poor-law Commission, and until that report had been issued and fully considered, boards of guardians would have to be careful before launching out into any great expenditure. They would always, however, have to deal with a certain number of phthisical cases and must make provision for them. It was also certainly their duty to take steps to prevent the spread of the disease from parents to children. The recent order of the Local Government Board, which made it obligatory on union medical officers to notify chargeable cases to the health authorities, was a step in this direction. It was subsequently resolved to appoint a committee of nine persons representing Lancashire and three representing Cheshire to take up the whole question, and to submit suggestions on which boards of guardians might act, for dealing with persons suffering from consumption or threatened with it.

THE NOTIFICATION OF BIRTHS ACT IN DARWEN.

The Darwen Corporation has not only adopted the Notification of Births Act, but has apparently made up its mind to administer it in a way offensive to the medical profession. On December 10th four defendants were brought before the Darwen magistrates for not notifying births within thirty-six hours. In one case a doctor said it was an omission on his part, and he was fined 5s. and costs. If that were the only defence made possibly no blame can be attached to the magistrates, as they were bound to carry out the Act. But in another case the defendant—not a medical man—complained that the doctor had not informed him of the necessity of early notification. The Clerk of the Court then asked the defendant if he meant to suggest that the doctor ought to have been summoned instead of himself, and when he replied in the affirmative, the Clerk said: "I think so, too." The Town Clerk explained that the defendant was liable unless he had a reasonable cause to believe that some one else was giving the notice, and the Chairman of the magistrates said that ignorance of the law was no excuse, and the defendant would be fined 5s., "for which," said the Chairman, "you can ask the doctor." It might almost be assumed that this was said in a bantering way; but the defendant did not take it so, for he said: "Can I have a magistrate's order for the doctor to pay the money?" To this the Clerk of the Court replied: "You can ask the doctor to refund it, and if he doesn't the Town Clerk will consider about summoning him." There is nothing in the Act of Parliament that makes the medical man any more liable than the father, and the remarks of the Clerk can only be taken as a deliberate attempt to read into the Act something that is not only not there, but something that was never intended. It seems to us that the Clerk distinctly exceeded his duty in making such a suggestion. It was prophesied over and over again when this Act was under discussion that there would be a disposition gradually to lay all the onus of notifying on the doctor, but even the most pronounced opponent of the Act hardly dreamt that such a barefaced attempt as this would so soon be made to strain the plain meaning of the Act. The decision of the magistrates to fine the defendant 5s. was of course strictly legal; it would have been strictly legal, too, to summon the doctor and to fine him if he had had no satisfactory excuse; but to suggest for one moment that a man not before the court, and with no opportunity of defending himself, was really the guilty party rather than the defendant who was actually fined, is surely a gross injustice and an abuse of the Clerk's position.

WEST YORKSHIRE.

BRADFORD ROYAL INFIRMARY.

THE Lord Mayor of Bradford, as is customary, provided the Christmas dinners at all the Bradford hospitals—the Royal Infirmary, the Royal Eye and Ear Hospital, the Children's Hospital, and St. Catherine's Home for Cancer and Incurables. Accompanied by a large number of the interested public, he made a round of the hospitals on Christmas Day. In a speech at the Royal Infirmary, the

Chairman of the House Committee for the first time appealed for support for the erection of an entirely new infirmary. The existing building, he said, was old, and a new building could be better equipped and worked with much more economy.

MEDICAL MEN AND MIDWIVES.

The case in which Dr. F. K. March, of Bradford, was charged at the Westminster Police Court on December 30th with knowingly aiding one Jane Emily Inglis, of Bradford, unlawfully and fraudulently to secure a certificate of admission to the *Midwives' Roll* is one which should be noted by all medical men. Dr. March has practised in Bradford for many years; his long and honourable career and high professional position are known to all his brethren in that city, and much sympathy is felt with him in the position in which he found himself placed. He had given a certificate to the woman that she had been in bona fide practice as a midwife since 1885, and was trustworthy, sober, and of good moral character; she was accordingly admitted to the *Midwives' Roll* in 1904, and remained thereon until March, 1908, when a report was made to the Central Midwives Board that she had been guilty of negligence and misconduct in the exercise of her calling. Inquiries then made showed that she had been tried at the Leeds Assizes for murder, the indictment alleging the death of a woman arising out of an illegal operation; she was convicted of manslaughter and sentenced to three years' penal servitude. Dr. March having no knowledge of these facts gave the certificate in good faith. The magistrate expressed the opinion that the Director of Public Prosecutions was justified in the course he had taken, as it was very important that the medical profession should understand that certificates of character of persons who desired to practise as midwives were not mere matters of form; that Dr. March had acted carelessly was unquestionable, but after the explanation given the case against him would be dismissed. The magistrate committed the woman for trial to the Old Bailey, bail being allowed. The case shows the necessity for the most careful investigation into the antecedents of persons applying for certificates.

LEEDS.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN IN LEEDS.
AFTER a good deal of discussion, and after hearing representations from various quarters, the Elementary Education Subcommittee of the Leeds Corporation has recommended the appointment of a medical officer to devote the whole of his time to the inspection of school children in Leeds at a salary of £350 per annum. They also recommended the appointment of medical practitioners to assist in the work. These must be prepared to devote one, two, or three half days in the week to medical inspection at a remuneration of one guinea for each half-day's service of thirty examinations. These posts are to be advertised.

Ireland.

[FROM OUR SPECIAL CORRESPONDENT.]

RESEARCH DEFENCE SOCIETY.

The Presidents of the Royal College of Physicians, the Royal College of Surgeons, and the Royal Academy of Medicine have addressed a circular letter to the members of the profession in Ireland, asking them to join in the formation of a Dublin branch of the Research Defence Society. The principal object will be to instruct the public in the facts and to show the purposes of experiments on living animals. Already a large number of lay members have intimated their willingness to join, among these being the Archbishop of Dublin, Right Honourable Viscount Iveagh, K.P., Right Honourable Lord Ashbourne, the Dean of St. Patrick's, the Bishop of Clogher, Very Rev. W. Delany, S.O., Sir Howard Grubb, F.R.S., Rev. Dr. Goynan, Regius Professor of Divinity, General Sir Neville Lytton, Viscount Monk, Archdeacon of Ardagh, the Bishop of Thom, the Earl of Pembroke, Sir A. Pöyten, Bart., late Master of the Rolls, Sir Frederick Shaw, Bart., the Provost of Trinity College, the Dean of the Chapel Royal, the Vice-Provost of Trinity College, etc.

THE NEW NATIONAL UNIVERSITY OF IRELAND.

The Gaelic League still pursues its campaign to induce the Senate of the National University to adopt Irish as a compulsory subject. Boards of guardians, county councils, corporations, and all sorts of public bodies have been enlisted in the crusade and are passing resolutions in support of the league's claims. Then there are many letter writers, of whom Colonel Maurice Moore, C.B., is perhaps the most emphatic. He says of those who are opposed to compulsory Irish:

They want a university to give a Catholic education to all English-speaking Catholics, whether English or Irish, Australian or American. Ireland is the selected site, because it lies between the two Continents, and Dublin is a convenient port; the Irish nation is an accident not worth considering among those other great peoples. . . .

What is it we want instead of this cosmopolitan university? We want, and we are determined to get, a university for Irishmen above all things, and for the Irish language. If the new university is not that, whether it is Catholic or Protestant, it is not for us: it is for the foreigner. And these demands are made not by any clique or league, but by the Irish people.

This struggle for a national university is a matter of principle, on which there can be no compromise: they are determined to fight the battle to the end and risk everything on the result. If the Senate refuses to make Irish compulsory for the matriculation of all Irishmen, there will be a five years' agitation against the new university, and every opposition will be made to the foundation of scholarships. Every anti-Irish senator will be marked down and his seat challenged at the next election, whether he be a Protestant, a Jesuit, or a bishop.

Mr. Charles Kennedy, chairman of Jervis Street Hospital, who died a couple of weeks ago at an advanced age, left a large sum of money. It is rumoured that the Provincial of the Jesuits in Great Britain and Ireland will benefit to the extent of over £100,000, but it is understood that it is intended to use this money for the erection of students' residences in connexion with the new university.

THE DISPENSARY SYSTEM.

Those of our readers who take an interest in Irish Poor-law affairs will recollect that some years ago the Irish Local Government Board decided to amalgamate three dispensary districts in the Ardee union into two, and to divide the salary of the abolished district between the two remaining medical officers because the guardians of that union would not give three medical officers a living wage. The Irish Medical Association took the case into court, but was defeated. A deputation from the village of Cullon, the centre of the absorbed district, and from the neighbourhood, recently waited upon the Ardee Board of Guardians to request it to try to induce the Local Government Board to revert to the former state of things, and we note that the guardians were willing to accede to the request provided they could deprive the existing medical officers of the additions to their salaries. The deputation urged as the reason for advocating a reversion to the old order the hardships inflicted upon the poor by having to go so much further for a doctor.

We referred some weeks ago to the dispute going on in Castlebar Union, where the guardians, having been defeated in their effort to upset the sealed order of the Local Government Board providing five dispensary districts for that union instead of four, have, we observe by the local papers, decided to appeal, but not unanimously. It seems time that the whole Irish dispensary service was reformed, in the interest not of those who, while able to pay, want their doctoring cheap, but of the real poor, "the ultimate peasant on the hillside," who has to depend upon State aid in his hour of need.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

NOTHING NEW TO REPORT.

SCOTTISH MEDICAL AND DENTAL DEFENCE UNION.

At the annual general meeting of the Medical and Dental Defence Union of Scotland, Limited, in Glasgow, Sir Hector C. Cameron occupied the chair, and there was a large attendance of members.

In moving the adoption of the annual report and statements of accounts, the Chairman remarked that the

accounts disclosed more marked progress than in any previous year. He referred to the statement submitted by the Council that a large proportion of threatened actions on being taken up by the Union were abandoned, and expressed the view that this illustrated the benefit of such an association. There could be no question that an association always suggested to persons considering proceedings that they would have a much more serious opposition than if they had to deal only with individuals. He also referred to the fact that the number of claims against dentists by dissatisfied patients was greater in proportion to relative numbers than in the case of medical men. The membership at the close of the previous year was 966; 240 new members were admitted during the year under review, being an increase of one-fourth. The Union had invested funds amounting to £1,204 9s., and the income for the year was £586, with an expenditure of only £270 15s. The Chairman thought that the members might congratulate themselves very much on these figures as showing that progress was satisfactory and consistent. Reference was made to the printed forms issued by the Union for the use of practitioners, there being an indemnity form to be granted by friends of patients in respect of lunacy certificates, and an agreement for use between practitioner and assistant. Dr. Crawford Renton seconded the adoption of the report and statement of accounts, and this was unanimously agreed to. The officers were re-elected as follows:

Presidents.—Sir A. R. Simpson, Edinburgh; Professor Stephenson, Aberdeen; Professor Sir Hector C. Cameron, Glasgow; and Professor Kynoch, Dundee.

Vice-Presidents.—Drs. Affleck, Berry Hart, and Murdoch Brown, Edinburgh; Professor Samson Gemmell, Glasgow; Drs. Crawford Renton and Parry, Glasgow; Drs. John Gordon, Scott Riddell, and Westland, Aberdeen; Mr. Greig, Dundee; Dr. McLachlan, Dumfries; Dr. Frew and Mr. Lipscomb, L.D.S., Kilmarnock; Dr. Ritchie, Dunoon; Dr. Graham Paisley, Dr. Laurie, Greenock; Dr. David J. Penney, Rochesay; Dr. Livingstone London, Hamilton; Dr. MacPhail, Coatbridge; Dr. Kennedy, Perth; Dr. MacAlister, Forfar; Dr. Curror, Kirkcaldy; Drs. Moir and Kerr and Mr. Fraser, L.D.S., Inverness; Dr. Clarke, Dumfries; Dr. Dale, Stranraer; and Dr. Ronaldson, Haddington.

Members of Central Council.—Dr. John Gordon, Aberdeen; Professor Kynoch, Dundee; and Dr. G. Balfour Marshall, Glasgow.

NEW INFIRMARY FOR PERTH.

At a recent meeting of the directors of the City and County of Perth Royal Infirmary, it was unanimously resolved to proceed with the erection of a new infirmary, to consist of 150 beds, at an estimated cost of £400 per bed. The chairman and deputy-chairman were requested forthwith to issue a circular appealing for £10,000, this sum being still required to complete the scheme, principally in consequence of subscriptions originally dedicated for reconstruction having been found to be not available for the scheme as modified by the directors.

Sydney.

[FROM OUR SPECIAL CORRESPONDENT.]

PURE FOOD AND QUACK MEDICINES.

At the end of 1907, just prior to Parliament going into recess, the Premier introduced a Bill into the Legislative Assembly providing for the purity of the food supply. The bill was subsequently scrutinized by commercial men and others, and several amendments were suggested. As a consequence of this, the bill was to some extent recast, and again introduced into Parliament in November, 1908. It consists of fifty-two clauses, but the whole purport of the measure is contained in one clause, which sets forth what is meant by food adulteration. This is defined in the following way:

(1) When it contains, or is mixed with or diluted with, any substance in any quantity or in any proportion which diminishes in any manner its food value or nutritive properties as compared with such article in a pure or normal state, and in an undeteriorated or sound condition; (2) when it contains or is mixed with or diluted with any substance of lower commercial value than such article in a pure state; or (3) when either wholly or in part it does not comply with a standard therefor prescribed by any regulation; (4) when it contains any substance prohibited by the regulations; (5) when it contains any substance concerning which any restrictive regulation has been made in excess of any quantity or

proportion permitted by such regulation; (6) when it is mixed, coloured, powdered, coated, or stained in a manner whereby damage or inferiority may be concealed; (7) when it consists wholly or in part of a filthy, decomposed, or putrid animal or vegetable substance, or of any portion of an animal unfit for food, whether manufactured or not; (8) when it is the product of a diseased animal or of one which has died otherwise than by slaughter; (9) when it is damaged, deteriorated, or perished; (10) when any valuable constituent of the article has been wholly or in part abstracted; (11) when it is in any package, and the contents of the package as originally put up have been removed in whole or in part and other contents have been placed in such package, or if it fails to bear on the package or on the label attached thereto, a statement of the quantity or proportion of any morphine, opium, cocaine, heroin, alpha or beta eucaine, chloroform, cannabis indica, chloral hydrate, or acetanilide, or any derivative or preparation of any substances contained therein; (12) when it is in package form, and the contents are stated in terms of weight or measure, and they are not correctly stated on the outside of such package; (13) when it is in package form, and the package or any label attached thereto, bears a statement, design, or device, regarding such article of food or drug, or the ingredients or substance contained therein, which is false or misleading in any particular.

Another clause provides that:

No person shall sell any article of food or any drug which is adulterated or falsely described, or which is packed or enclosed for sale in any manner contrary to any provisions of this Act.

Another clause prohibits the sale of injurious drugs. The bill would give the Governor power to prohibit, by notification in the *Government Gazette*, the advertising or sale of any food or drug which, in the opinion of the Board, is injurious to life or health; it further forbids newspapers to publish any advertisement prohibited under this clause. As regards quack medicines, power is given to the Government to examine these articles, and to compare the results of the examination with the results spoken of in the advertisement. If the results of the analysis do not support the advertisement, the Government may cause this report to be published. Provision is made for the appointment of an advisory committee to assist the Board of Health on all practical scientific questions. This committee is to consist of a proportion of purely scientific members, with a departmental element giving the Government representation, and power is given for representation of the active practical training interest—the Chamber of Commerce and the Chamber of Manufacturers, and not more than three persons conversant with trade requirements. This bill is now under discussion in Parliament, and as it is one which appeals to all classes as a very necessary measure it is most probable that it will pass practically in its present form.

Special Correspondence.

EGYPT.

Cairo Main Drainage.

In view of the fact that so many people are now sent to Egypt each winter for reasons of health, a large proportion of whom are compelled to make a short stay in Cairo en route to the various desert health resorts such as Helouan and Assuan, a few facts as to the proposed drainage of Cairo may be of general interest. Mr. Carkeek James, the Controller-General of the Cairo Drainage Works, who has been connected for many years with drainage schemes in the Far East, where conditions similar to those of Cairo prevail, has for more than eighteen months studied the problems connected with the Cairo drainage. His final proposals have received the entire approval of the Egyptian Government. Owing to the general flatness of the plain in which Cairo is situated, and to the fact that a suitable site for sewage purification works can only be obtained at a considerable distance, it is impossible to drain the city without pumping being resorted to. A certain small area can be drained by gravitation to the main collecting sewer, but the remainder of the city must be drained on the "sectional system"—that is to say, this area must be subdivided, and the sewage from each such subdivision must be lifted by suitable means, and discharged into the main collecting sewer. In Cairo, the number of days in the year on which rain falls is small, but after even a moderately heavy downpour there is a large amount of surface water to be disposed of. To allow this to enter the sewers would involve heavy expense, not only because

all sewage will have to be artificially lifted one or more times, but also because the sewers, pumping machinery, etc., would have to be increased in size. The station for generating the power for driving the lifting arrangements in the area drained on the "sectional system" will be situated at Pont Sabel and, as there is no nuisance in connexion with a power station, its proximity to good buildings is not objectionable. The main collection sewer will start at Pont Ghamra and follow the new road to Teftiche el Koubbel, thence along the Metarich to Ein el Chams and from there it will follow the Gebel Canal to the main pumping station, which is to be about a kilometre to the east of the village of Kafr el Gamous. From the main pumping station, the rising main will continue along the south bank of the Gebel Canal and of the Alexander Canal up to the point where this latter makes a right angled bend to the north-west. From here it will go across the desert to the site of the purification works at Khanka, where 25 kilometres to the north of Cairo it is proposed to lay out a sewage farm. All existing cesspits and soakaways are to be abolished in order to put a stop to the pollution of the subsoil and sanitary fittings which, in the case of the native population, will be specially designed to conform with their habits and religious customs, are to be introduced. With regard to the branch sewers, best stoneware pipes will be used and every precaution taken to ensure all being watertight. The trenches in the wider streets of the city will in no case exceed 5 metres in depth and in the narrower streets 3 metres. There is, it is said, a strong feeling in Europe and elsewhere that the excavation of the ground for this scheme is going to lead to much ill-health, but the best authorities on the subject agree that there is no need for anxiety on this account, since the trenches for the sewers will not only be narrow, but also shallow, and the amount of excavation required for them will be small in comparison with the large areas of ground that are now being constantly opened for the construction of hotels and buildings. Moreover, all material excavated on the works will be at once removed, by means of overhead cableways, to the trenches that are being filled in, any surplus material being at once disinfected and carried away. So far as tourists are concerned and those responsible for advising a winter residence in Egypt, it should be noted that no work will be done during the tourist season, as that corresponds with the high Nile, which influences the height of the subsoil water. The excavation work for the sewerage of the city must be carried on in summer, when the Nile is lowest and the subsoil water accordingly at its minimum height.

Correspondence.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

SIR,—A perusal of the report of the Education Committee of the London County Council on the medical treatment of children found to be defective by the Medical Inspectors in the Public Elementary Schools, which was published in the *BRITISH MEDICAL JOURNAL* of December 26th, pp. 1869-1874, must fill all ratepayers with dismay.

I have no less sympathy for the half-starved, ill-clad, hygienically housed and consequently diseased children attending the schools, than is felt by any member of the committee, but such sympathy should be tempered by a sense of justice to the general body of citizens, and by a statesmanlike attempt to consider the whole question of political economy involved. I therefore view with alarm the recommendations of the committee, for, if carried into effect, I believe there will be great and unnecessary waste of public funds, in consequence of the proposed scheme overlapping with the ample machinery already in existence, for dealing with those who are unable to pay medical fees in the event of sickness.

I gather from the report that it is proposed: (1) To send all children requiring in-patient treatment to the voluntary hospitals; (2) that "the Council should utilize existing types of institutions, giving financial help if necessary," for all the other children not included in Recommendation (1); (3) that "in districts where there is

no prospect of utilizing existing institutions" the Council should erect and suitably equip school clinics or surgeries.

The first proposal, namely, to send all children requiring in-patient treatment to the voluntary hospitals without payment, is a matter for the boards of the various hospitals concerned, but I believe it will prove to be a burden greater than they can bear, if they are to be sufficiently considerate of the claims of the rest of the community.

The second proposal, namely, to send all the remaining children to the out-patient departments of the voluntary hospitals and to subsidize such as are suitable, is not only unsound in principle but is unjust to the hospital subscribers, to those who seek hospital relief, and to the medical men who attend them. It is unjust to those who have given money to endow hospitals or contribute to their support, because they do so, not with a view to relieving the State of responsibility—a responsibility only just recognized—but they give it for the relief of the urgently sick who could obtain extraordinary and proper treatment in no other way. It is unjust to the medical profession, because the ground upon which the services of the honorary staff of a hospital or other charitable institution are given to it, is that it is a charity supported by the voluntary contributions of benevolent members of the community. If this charitable basis be abolished, the claim upon the staff to act as honorary officers ceases. If hospitals accept contributions from public funds in consideration of undertaking the treatment of certain patients, then, as regards the treatment of those patients, they cease to be charitable institutions. If these grants be made to the hospitals for services rendered, it will give rise to such difficulties as to the particular individuals who should receive the payment as to render the scheme impracticable.

The general question as to whether the hospitals should be subsidized by the municipality is another matter. Personally, I should welcome it, as being the thin end of the wedge towards the entire municipalization of hospitals, which is eventually bound to come.

The third proposal, embodied in the rider to the second proposition, namely, to provide school clinics "where within a reasonable time there was no prospect of utilizing existing institutions," although comparatively innocent at first sight, is in reality a far more serious matter than is doubtless generally realized by the ratepayers. It will necessarily involve a large capital expense, because a glance at the map of the county of London, on which existing voluntary hospitals and dispensaries have been marked, and which I understand is published elsewhere in this issue of the *JOURNAL*, will show that while these institutions are crowded together in the centre, yet towards the periphery they become fewer and fewer in number, until some large areas are left entirely without them. It follows, therefore, that if the committee's recommendation be acted upon, a large number of these school clinics will be established in the near future in this outer ring of London. I submit, however, that the institution of such school clinics is unnecessary, because the machinery of the Poor Law already exists for the relief of those who are too poor to pay for medical treatment, no district of the metropolis being unserved by an infirmary and a staff of district medical officers.

If the public, who have to pay heavily for the various institutions under the Poor Law, had any idea of how ample and excellent this provision for the sick poor is, they would not entertain for a moment the suggestion to multiply still further the already large number of hospitals (Poor Law infirmaries), and other institutions supported entirely out of the rates, where this new work for the school children could be undertaken quite easily, under the auspices of the Poor Law, with but slight increase of staff and modification of already existing buildings, at a comparatively small cost.

For those who know little of the workings of the Poor Law I may say that in my own constituency—the Union of St. George Hanover Square—the ratepayers provide for the sick poor an infirmary (in other words, a hospital) containing nearly 800 beds. This institution has an ample staff of resident doctors and trained nurses, is lighted and warmed on the most modern principles, is equipped with an operating theatre, far better than can usually be found in nursing homes to which rich patients have to go, and could further be equipped with any additional apparatus which the Education Committee might dictate, at the

smallest possible cost. All this is in addition to the provision for the sick inmates of the adjoining workhouse, which accommodates 1,700 persons; and to the lying-in wards; to the staff of district medical officers who visit the sick poor in their own homes; and to a dispensary where the poor can be seen or send for medicines. I have quoted only one Union, but all the other metropolitan Unions are similarly and quite as well equipped.

Over and above all this the Metropolitan Asylums Board provides special schools for ringworm, on the Downs near Sutton, Surrey, which were erected on a site of nineteen acres at a capital cost of £107,000; this school is by no means well filled, although, in addition to the resident staff, a skin specialist attends and undertakes the latest treatment of the disease referred to by the Education Committee—namely, the x rays.

Special schools for eye diseases under the Metropolitan Asylums Board are also provided at Brentwood on the cottage home plan, on a site of 23 acres, at a capital charge of £107,575 for 300 children; and at Swanley, also on the cottage home plan, on a site of 49 acres, for 300 children at a cost of £128,613. An eye specialist attends both schools, but neither is by any means full. Homes for convalescent children are provided at Heme Bay, Margate, and Rustington. At Heme Bay on 2½ acres, at a cost of £17,249, for 134 children; at Margate on a site of 1½ acres, at a cost of about £20,000 for 130 children; and at Rustington on 5½ acres, for 120 children at a cost of £36,000. Five homes for mentally defective children have been provided in various parts of London, and one on a site of 7½ acres at a cost of £13,000 at Witham, Essex.

In view, therefore, of the various excellently equipped infirmaries scattered all over London, few of which are full, and in view also of the ample accommodation of the Metropolitan Asylums Board for the special eye and skin diseases referred to by the Education Committee, it seems to me that it would be an unwarrantable waste of public money to erect or adapt yet other buildings for use as school clinics. I have the greatest respect for the London County Council, but they prove that they ignore or make a clean sweep of existing things, and prefer rather to start their new schemes with everything new from the beginning.

It seems to me far more practical to open a sort of out-patients' department at every infirmary in London—call it school clinic if preferred—where the school children could attend for treatment. The more ill ones could be admitted to the wards straight away, and the less ill ones sent back to their homes or to the school after treatment. Of course it would be necessary to increase the nursing and medical staff, but this could best be done by having a sufficiently large number of part-time non-resident officers who would work in shifts. If this system were extended to the voluntary hospitals it would put an end to the overcrowding and abuse of hospital out-patient departments, since all the cases not suitable for teaching students or needing the knowledge of experts could be drafted on to the proposed out-patient departments of the infirmaries.

The scheme outlined above would be the best—and, to my mind, the only practical one—for preventing the abuse of public funds by those able to pay for themselves. Under the existing Poor-law regulations medical relief is given, where possible, only as "relief by way of loan," the cost of which is recovered in weekly payments from those receiving it; or, if the recipients state that they are too poor to pay, their circumstances are verified by the relieving officers who visit them in their own homes and are therefore in a better position to advise as to the true facts of a case than any hospital almoner can possibly be. An even better plan than that of increasing the numbers of relieving officers would be to combine the duties of school nurse with that of relieving officer; for it is clear that a large number of extra nurses will be required to visit the children actually under treatment in their own homes. Lay visitors of the various health societies and other charitable organizations could do much useful work by undertaking part of this duty, to the benefit of the poor, to whom they could impart some knowledge of the elements of hygiene, and to the rate-payers, who would thus be saved the expense of additional relieving officers.

The objection to this scheme that will doubtless be made is that anything received from the guardians carries

with it the "stigma of pauperism." But this objection is invalid since Poor-law medical relief involves no disfranchisement. It is also illogical, for the poor are pauperized far less by being given medical relief out of the rates, to which they themselves contribute or have contributed, than by being given this relief at a voluntary hospital gratis, out of the charity of the medical profession and of the rich—regardless of whether they can pay or not. Finally, I believe that the finding of the Poor-law Commission will remove the objection altogether, since it is an open secret that the new classification of the poor which they will recommend will absolutely dissociate medical relief from other forms of relief, and the genuinely poor from the vagrants. Whether this will prove to be the case or not, I appeal to the Education Committee to take no decisive action in this matter and embark upon no new scheme until the publication of the report of the Royal Commission on the Poor Law.—I am, etc.

THE DRAFT CHARTER AND THE REFERENDUM.

SIR,—I venture to state that no more astonishing letter from a President of the Association than that in your issue for January 2nd has ever appeared in the columns of the JOURNAL.

In his letter Mr. Simeon Snell explains how he, in his official capacity as President of the Association for the current year, has done what he could to put himself in direct opposition to the action taken by the Council, on behalf of the Association, in accordance with resolutions of the Representative Meeting, which, confirmed as they were by the Council, constitute, in the language of our present regulations, "decisions of the Association." The logical inference to be drawn from the President's action in withholding his signature to the petition to the Privy Council for a Royal Charter of incorporation is, not that he wishes to obtain certain modifications in the text of the Charter—of which modifications we have heard so much of late—but that he is using his official position to prevent the Charter being granted at all. It may be denied that this is the correct view to take of the President's action, but I would still hold that it is the only one which is justified by the facts of the case.

To be obliged to write this letter is most distasteful to me, but I felt that it was necessary to enter a protest against such a regrettable use of the Presidential office, the most distinguished post which the Association is able annually to bestow on any one of its members, and an honour which is conferred not by reason of previous service rendered to or experience of our Association in its central administration and government, but in consideration of the prominent professional and scientific position enjoyed by the member in question in the locality in which the annual meeting is held.—I am, etc.,

H. A. BALLANCE,
Deputy Chairman of Representative Meetings.
Norwich, Jan. 5th.

SIR,—In the agitation that has been going on for some time throughout the country on the above subject the By-laws of the Association seem to have been forgotten, or at least to have been treated with scant respect. We hear of individual Branches preparing to oppose officially the present Charter before the Privy Council; and even, where this is not done, there have been not a few instances of Branch meetings specially convened for the sole purpose of directing its council to follow in the footsteps of the South-Western Branch. All this, in my opinion, is diametrically opposed to By-law 7. There it is laid down clearly that the "management of the affairs of each Branch shall be vested in a Branch Council, and by what authority certain Branches have taken—to say the least—most revolutionary steps it would probably tax the ingenuity of the promoters thereof to clearly set out. If the view I have above stated should be legally upheld, another question must inevitably be asked: What about the expense incurred by these Branches for illegal objects? By-law 16 is pretty clear on the

financial aspect. "Out of the money received, etc., . . . the Branch shall defray all its expenses," etc. This can only mean legal expenses; and if a Branch can legally only manage its own affairs, to spend money on matters affecting the Association as a whole must be illegal, especially when there are properly constituted authorities for that purpose.

I note with regret our President's letter in the *JOURNAL* of January 2nd. I had thought that it was the duty of any one holding his high position to give effect to the voice of the Association, as expressed through its constitutional and official mouthpiece, and not to be swayed by his own predilections, or by those of irresponsible parties within the Association. This I have always observed in the case of the presidents of other associations, but unfortunately here, as in some other recent cases, the customs and usages of the outside world are too little regarded within the ranks of our Association.—I am, etc.,

London, N.E., Jan. 2nd.

MAJOR GREENWOOD.

SIR,—Before and after the meeting of the members of the Metropolitan Counties Branch called to decide whether steps should be taken to oppose the application for a Charter several asked details as to the twelve and twenty-four members to be elected to the Central Council.

The following facts were given in answer to questions. Other questions that were asked I trust you will allow to be put to those who have raised the present discussion; they show the line along which many members are thinking.

The replies are being awaited; and as the questions were put by moderate men who seem desirous to take an intelligent interest in the Association, may a hope be expressed that some one will answer them?

	12 Members.	24 Members.
How is the United Kingdom to be divided to elect these 12 and 24 men respectively?	Into 12 single member constituencies.	Into 23 single and 1 double member constituencies.
Who will be the candidates in a constituency?	Any member resident in the constituency.	Any member resident in the constituency.
Who will be the nominators in a constituency?	1. Branch Councils in the constituency. 2. Divisions in the constituency. 3. Any 10 members in the constituency.	1. Divisions in the constituency. 2. Any 3 members in a constituency.
Who will be the electors in a constituency?	The Representatives of Divisions in the constituency (no doubt acting as instructed by their Divisions).	The members resident in the constituency.
Are any Representatives of the Branches on this Central Council at present members of the Representative Meeting?	—	Yes.
Are any of these 12 and 24 men likely to be members of the Representative Meeting?	Yes.	Yes.

1. Why do they say that the Representative Meeting will elect these twelve men?
2. Why will these twelve men be more likely to support the Representative Meeting as a whole than many or all of the twenty-four men?
3. Why were these facts, if correct, not stated by the country Branch Councils in their recent circulars?
4. Why don't they allow the Medical Secretary to state the facts, and then we should know where we are?
5. If a half to be present with a two-thirds majority of them is good enough for the Representative Meeting, why is it not good enough for the Central Council?
6. What has all this discussion to do with obtaining a Charter?
7. What is behind it all?
8. Will the house-to-house Referendum help the Association to do more for the general practitioner? Will it put down hospital abuse?

—I am, etc.,

London, S.W., Jan. 2nd.

E. ROWLAND FOTHERGILL.

SIR,—There is an argument which is being strongly urged in some quarters against the action of the South-Western Branch and others in the matter of the Charter

—namely, that to petition for amendment of the Ordinances at the present time will stultify the Association in the eyes of the Privy Council and the public.

I venture to suggest that nothing could be more derogatory to the Association than the lodging of a petition of such moment as one for the grant of a Charter, which lacks the signatures of the three highest officers of the Association—the President, Past-President, and President-elect. It is inexcusable, and the absence of the signatures of these three gentlemen is scarcely likely to escape the attention of the Privy Council—a member of which is, by the way, one of the signatories.

The amendments to the Charter in reference to the Referendum and election of Representatives brought forward at the Sheffield meeting of the Representative Body ought at any cost to have been referred to the members of the Association and a vote taken on them. Better a year's delay in obtaining the Charter than such deplorable action as has been taken by the Council.—I am, etc.,

Putney, S.W., Jan. 2nd.

A. DE WINTER BAKER.

SIR.—The members of the Edinburgh Branch were sent the following post-card:

Do you approve of the Branch Council taking the necessary steps to lay before the Privy Council their view that a Referendum should be taken on the requisition of half the Council, and then by letter addressed to every member of the Association?

The following replies have been received:

Approvals...	...	231
Disapprovals...	...	2
From home...	...	1
Members of Branch...	...	413

We are, etc.,

A. LOGAN TURNER,

FRANCIS D. BOYD,

Honorary Secretaries.

Edinburgh, Jan. 4th.

THE BIRMINGHAM BRANCH AND THE COVENTRY PROVIDENT DISPENSARY.

Testimonial to the late Medical Officers.

SIR,—Eighteen months ago, in response to representations from the Coventry Division, supported by the Birmingham Branch of the British Medical Association, four of the medical officers of the Coventry Provident Dispensary resigned their posts, because they failed to obtain alterations in the rules that were considered necessary in the interests of the profession. Unfortunately, other medical men were found willing to take their posts, in spite of a full knowledge of the causes of the resignations.

In the result the four medical men have sustained considerable pecuniary losses. One has been obliged to leave Coventry for financial reasons; another has experienced serious diminution in his professional income; while a third, Dr. Hird, died in November, 1907, his death being undoubtedly hastened by worry and financial anxiety. Mrs. Hird is left in very straitened circumstances.

The Council of the Birmingham Branch are unanimously of opinion that, in the interests of the Association and of professional unity, a fund should be raised, in the first place to assist Mrs. Hird in her difficulties, and in the next to make presentations to the medical men in token of the approval and sympathy of their professional brethren.

A grant has been applied for from the Central Emergency Fund of the Association.

Since this matter seriously affects the *esprit de corps* of the profession, the Branch Council earnestly appeals to every member to send a contribution to the Honorary Treasurer of the Branch, Dr. Thomas Wilson, 87, Cornwall Street, Birmingham.—We are, etc.,

FRANK MARSH,

President.

ALBERT LUCAS,

J. FURNEAUX JORDAN,

Honorary Secretaries.

TWO BRAVE WOMEN DOCTORS.

SIR,—The story of the Hyderabad flood has now been overshadowed by that of a far more appalling disaster. Nevertheless the catastrophe that befell the capital of H.H. the Nizam's dominions, three months ago, was of terrible magnitude, and the details published in the newspapers cannot yet have faded from the memories of your readers. The incidents of greatest interest to the medical profession were the destruction of one of the two large hospitals and the flooding of the other, with the saving of its inmates by the resident women doctors, aided by the nursing staff. It is because I think that little attention has been drawn in the medical journals to the heroism of these ladies—though their names were cheered to the echo at the recent Mansion House meeting—that I venture to address this letter to you.

Miss Pinto and Miss Correa, both young women—the latter only obtained her diploma two years ago—were at the time of the flood the resident medical officers of the Victoria Zenana Hospital at a group of beautiful buildings, the corner stone of which was laid by H.R.H. the Princess of Wales. It is unnecessary to repeat the accounts of how, after five days of incessant rain, the water of the river rose, and how eventually the Zenana Hospital was completely surrounded and cut off from all succour: even communication between it and the opposite side of the river being lost. Miss Pinto and Miss Correa had been repeatedly warned of danger by the police authorities of the city and urged to leave, but they refused to evacuate the hospital without orders, or to abandon their patients and their charge. Night came on, and the water still rose, until the danger of which they had been warned became imminent. With the help of the nurses they carried all their patients to the flat roofs of the blocks, contriving for some a partial shelter, a labour not completed until 1 o'clock in the morning, when they, with the whole of the staff, took refuge, though without a particle of shelter, by the sides of those they had saved. Sixty-five women in all crouched in terror throughout that dreadful night; the rain continued to pour on them in torrents—the flood actually rose to within a few inches of their last possible and perilous position, and through the darkness came the crash of falling houses and the despairing cries of drowning people. Dawn brought neither comfort nor relief; all around them was a sea of roaring water; wreckage and heavy beams of timber dashed against the walls of the buildings, which shook at every fresh impact. Death threatened at every moment. A dreadful day succeeded a dreadful night, and it was not until late in the afternoon that the rain slackened, and the flood subsided even more rapidly than it had risen.

In the dusk of evening a small band of rescuers managed to reach the hospital, and eventually with great difficulty, and after hours of labour, got the party down from the roofs to a place of safety, drenched, exhausted, and fainting. Miss Correa's condition was particularly pitiable; her health had been very delicate for a long time before, and the exposure had for immediate result a long and dangerous illness, from which she has not yet recovered. The resident medical officers' quarters, an older and unsubstantial building, collapsed completely, and every thing the lady doctors possessed went down the flood.

My knowledge of the circumstances is not derived from newspaper reports, but from the unanimous testimony of private correspondents at Hyderabad. I hope, Sir, that you and your readers will agree with me that these two physically weak young ladies, one herself an invalid, showed devotion to duty and courage worthy of the best traditions of our profession, and that their names deserve a place in the records of its noble deeds.—I am, etc.

G. H. D. GILLETTE, Lieutenant-Colonel, I.M.S.

(until lately Director of H.H. the Nizam's Medical Department).

THE FLEA AS A CARRIER OF PLAGUE.

SIR,—In the *Proceedings of the Society of Tropical Medicine*, reported in the *JOURNAL* of January 2nd, there is a very abbreviated report on an historical incident bearing on the possible spread of plague by the agency of the flea.

The incident is as follows: On the defeat of the Israelites by the Philistines, when the two sons of Eli,

Hophni and Phineas, were slain, the Ark of God was taken, carried to Ashdod, and lodged in the temple there. An outbreak of pestilence followed, and, owing to it, the Ark was sent to Gath. There, again, plague occurred, and "he smote the men of the city, both small and great, and they had emerods in their secret parts." Whereupon the Gathites forwarded the Ark to Ekron. "And it came to pass, as the Ark of God came to Ekron, that the Ekronites cried out, saying, They have brought about the Ark of the God of Israel to us, to slay us and our people." "There was a deadly destruction throughout all the city." This plague was evidently of a very acute nature, and not bubonic only, for "the men that died *not* were smitten with the emerods."

These three outbreaks, ascribed to the Ark, thoroughly frightened the Philistines, so that they determined to send back to Israel the captured trophy. They arranged to give, as "a trespass offering," golden images of the things which struck the observation of the people most as connected with the outbreak. They had noted (a) the emerods (buboes) on the sick, and the presence of a plague of (b) mice (the Hebrew has only one word for rat and mouse—*akhbar*) that marred the land. Five golden "mice" and five golden emerods, placed in a coffer, accompanied the Ark, which was dispatched on a new cart drawn by milch kine. These took the straight line over the frontier to "the way of Beth-shemesh." The journey from Ekron to Beth-shemesh was about 12 to 14 miles, and the cart, at the end, was unaccompanied by the Philistines. There was no human contact. The kine, "lowing as they went," arrived in the field of a Beth-shemite where the wheat was being cut. The people were rejoiced. They made a burnt-offering of the kine, using the wood of the cart for fuel. The Ark being taken aside, curiosity prompted some to look within it. "Punishment" followed, and fifty thousand three score and ten men died for this "offence!"

The points in the story are:

1. Plague was raging at Ashdod.
2. In its temple rats would swarm, as in such buildings at the present day in India, owing to the amount of food of all sorts thrown about.
3. The Ark with its trappings—that is, its three coverings—was interned in the temple.
4. Its coverings were (a) "a rail of blue and purple and scarlet"; (b) a "covering of badger skins"; (c) "a cloth wholly of blue."
5. The middle covering of badger skins would thus form an ideal place of refuge for the fleas escaping from the rats dead from plague.
6. Outbreaks of pestilence followed on the arrival of the Ark at Gath and Ekron. At both these places human contact entered also.
7. Since no Philistines went with the Ark to the field of Joshua the Bethshemite, there was no human contact in that instance.
8. Looking into the Ark involved removing the trappings, and hence a disturbance of the fleas in the badger skins.

9. This historical incident I suggest as demonstrating the active part played by the flea in the spread of plague, since it bears strongly with the valuable work of the India Plague Commission on this subject.

In the *Literary Supplement of the Times*, December 31st, 1908, a reviewer of Butler's "Characters" quotes—and here is the suggestion of a controversy not extinct yet—"fifty thousand Bethshemites were destroyed for looking into the Ark of the Covenant, and ten times as many have been ruined for looking too curiously into that book in which that story is recorded."

Sir, I suggest that modern science has afforded an explanation for the singular event mentioned, and has thus cleared, in a natural way, what to many has been a stumbling-block in understanding the severity of this "punishment." Many years ago, whilst travelling in the neighbourhood of Beth-shemesh and Ekron it seemed to me a "hard saying." In 1896 I brought to the notice of a high church dignitary the explanation of the mice and emerods. He did not receive it as it was meant! I trust I am not following "too curiously" this subject, lest some may say "after whom dost thou pursue? after a dead dog, after a flea?"—I am, etc.

London, W., Jan. 15

R. HAVELOCK CHARLES.

THE MUMMIFICATION OF CANCER.

SIR.—I have just read the article which you devoted to my method in your issue of December 12th, 1908. If I have not replied to it sooner, it is because I have only just seen the number in question. I am persuaded that your only desire is to get at the facts, and that is why I now write you.

Of that desire I see evidence in your statements respecting my professional status. However desirous I might be to serve you in this respect, I should hardly feel inclined to personally recount to you the details of my works, which you sharply appreciate. Suffice it to say that Professor Lannelongue, who, in 1906, presented my *Treatise on Operative Technique* to the Paris Academy of Medicine, stated, *inter alia*, that "M. Laurent has published valuable and learned works, certain of which have been presented to the Academies of Medicine and Science of Paris, and on which I build hopes of one day seeing conferred upon him the title of Correspondent."

Let me point out, in the first place, that the value of my method does not consist in the mere fact of the use of formol, but rather in the enormous doses and in my manner of using the product. These form a method, a system, which I feel entitled to claim as my own.

You are not convinced of the efficacy of this system. You are entitled to doubt until you have a clear demonstration of the statements placed before you. Like all true scientists, you consider that a clear array of facts should alone carry conviction. So far, you are right. I am prepared to supply you with these facts by means of two series of demonstrations in London. First, by applying my method to, say, one hundred cases, rendered easily observable to medical men, students, and relatives of the patients.

As my stay in London would necessarily be limited, I suggest that the medical men should, in the course of the next two months or so, get together a hundred cases of ordinary external cancer, so that the progress of the treatment may be followed by all. These cases should be taken from three hospitals, and from private institutions as well. They should include cancer and sarcoma of the limbs, facial cancer, maxillary sarcoma, cancer of the lip and tongue, sarcoma of the neck, and cancer of the breast. The condition of the patient should be such that a surgeon could eventually undertake to perform an operation. In several cases therapeutic results would be observed as early as the fifth day. Before and during treatment the photograph, radiograph, temperature, and weight of the patient would be taken; his heart, blood, and urine would be examined.

The second series of demonstrations—comprising complicated cases, internal ones included, strength being sufficient—would be held at some subsequent date.

The term "success" must be defined. I recently stated that seventy successes were obtained by Fenwick out of nearly a hundred cases treated by him with bichromate. That is all right. By the term "cure" is implied a clinical cure; for a cancerous subject should, more than a syphilitic one, continue to be examined several times a year.

When we remember that formol may be administered in such heavy doses—10, 20, and even 50 grams—that it is a far more powerful antiseptic than sublimate, and that it is a first-class fixing agent, then the results achieved cease to astonish us. But the technique, though easy in some cases, is comparatively complicated in others. Therefore we must possess: First, a thorough knowledge of anatomy; and, secondly, previous experience in several typical cases. Given these, and being warned against disappointment, medical men will, I believe, be able to profit by my demonstrations, carried out in their presence.

Seeing the progress accomplished by operation, the x-rays, radium, electricity, and so on, we can hardly doubt that we are on the high road to the cure of cancer. While we are doubtless still far off the day when the cure of cancer will be effected by merely swallowing a few tablets, I still think that a fair hearing should be given to all substantiated claims of progress in therapeutics. I claim that my system of *formolization*, *mummification*, or *embalming*, and sometimes *fibromatosis*, does constitute progress. (I have even applied it, with a modified technique, to cases of tuberculosis.) Under these circumstances, and to whatever extent it may have been rendered

effectively applicable, I venture to think that you would declare yourself satisfied after following my demonstrations.

Inasmuch as cancer constitutes a grave social danger, not only because of the thousands of lives it destroys every year, but also by reason of the nervous dread of those who live in constant fear of its onslaught, I deemed that I should be rendering some slight service to my fellow countrymen by laying before them the principal facts. I therefore had printed at my expense an illustrated sheet describing cancer; I had 25,000 copies distributed, especially among local sanitary authorities and charitable societies, all over Belgium; and I should have liked very much to have supplied every family in the land with a copy.

In conclusion, Sir, I rely upon your acknowledged sense of justice to give this letter the same publicity which you accorded to the article of which it treats.—I am, etc.,

Brussels, Dec. 24th, 1908.

Professor Dr. O. LAURENT.

*** As our attitude to the cancer question has often been misunderstood and sometimes misrepresented, we take this opportunity of stating emphatically once more that our sole object is to prevent, as far as lies in our power, the profession and the public from being misled by unfounded hopes. What is wanted is not rumours and assertions of cures, but irrefragable proof. This can only consist in a sufficiently large number of facts that will bear the closest analysis, and in that analysis it must not be forgotten that accurate diagnosis is an essential factor. The element of time must also be taken into account. In regard to these points we make no distinction between surgical and medicinal or chemical treatment. Professor Laurent makes a sporting offer, but he must know that we have no power to compel hospitals to supply him with patients. He should apply direct to any three London hospitals of good repute; we venture to suggest that the Middlesex should be one of them, as it has a special cancer department and every provision for the testing of new remedies. He might also apply to the Imperial Cancer Research Fund, the directors of which would doubtless help him in getting an opportunity of fully testing his treatment. As for ourselves, we only hold a watching brief; but we assure Professor Laurent that if his method is proved to be successful, though it were only to the extent of materially palliating cancer, nowhere will his achievement find a heartier welcome than in the BRITISH MEDICAL JOURNAL.

SURGICAL TREATMENT OF CHOLELITHIASIS.

SIR.—In the JOURNAL of December 19th, 1908, under the above heading, Hans Kehr (page 93 of the Epitome of Current Medical Literature) is quoted as furnishing to the general practitioner various statistics so that he may be able "to tell his patient, whom he advises to submit himself to the surgeon, what the chances of operative treatment are." His own operations of various kinds number 1,309, out of which number there are altogether 225 deaths, or a percentage of 17.18—that is, roughly speaking, nearly one-fifth—of which it is only fair to say the greatest mortality was in the malignant cases, which amounted to 82 per cent. Deducting the two groups in which the mortality was the highest, "he had 891 operations for uncomplicated gall stones, with 29 deaths—that is, 3.2 per cent." Again in this most extraordinary article, "after dealing with some general considerations with regard to the operations, such as the frequency with which he carried out hepatoxomy [whatever that may mean] in his 'ectomy' operations"—your report was good enough to put the word "ectomy" in inverted commas—"as well as the frequency in which he removed the vermiform appendix when this organ, even if quite healthy, protruded into the wound, he discussed the cause of death."

Now, Sir, I am not an operating surgeon, but how any one with the slightest notion of elementary anatomy and the topography of the abdominal organs can conceive of the possibility of an operating surgeon, in the course of an operation for gall stone, finding "the vermiform appendix protruded into the wound" passes my wit to understand, and vitiates the whole value of the article, even if it did not stand self-condemned in many other particulars. I will not touch on the morality of an operator who, while

undertaking a serious and important operation, complicates that operation by a totally unnecessary interference with what he himself describes as an organ "quite healthy," and so risks the success of his primary operation and further imperils the life of his patient. Again, Sir, this heroic operator, who in the course of one serious operation performs another, as it were, takes it in his stride, gives the general practitioner advice as to "when the proper time has come to hand his patient over to the surgeon." Kehr "is convinced that not more than 20 per cent. of gall stone patients need be operated upon." He does not even suggest when the general practitioner has failed in his efforts to assist the passage of the [stone *per vias naturales*] that this bewildered practitioner should call in the assistance of a consulting physician who may be more experienced than himself in the ways of humouring and coaxing the offending stone through its natural passages and who may have spent many years of study with that object. No! no further chance must be given to the patient, but he must there and then be handed over to the brutal arbitrament of the knife and to the tender mercies of a surgeon who, not content with performing the operation he set out to do, may also indulge in the penchant he evidently has of removing perfectly normal and healthy organs. Truly the old book was wise when it said, "Oh! that mine enemy would write a book!" Now to criticize the statement that not more than 20 per cent. of the cases of gall stones need be operated upon. I have now been in practice many years, and in the course of that time have met with numerous cases of gall stones, and in only one case has it been found necessary to have recourse to operation—a case where Mayo Robson removed from a patient of mine a gall stone which was impacted in the common bile duct. In the early part of my career I made a collection of gall stones which had been passed by my patients through the ordinary channels, and got together a small bottleful of various sizes, from that of little more than sand to some specimens as large as a full-sized marble; and one I remember, which took two full days to pass, was even larger than that, and consisted of an agglomeration of several calculi agglutinated together, which it seemed almost impossible could have been passed through the bile duct, and proved to me that the elasticity and distensibility of that duct was far greater than it had been given credit for. Another point which Kehr in his article does not seem to me to have given any thought to is the fact, which is well known, that certain patients—often stout women of middle age and lethargic temperament—are very prone to pass gall stones at more or less regular intervals. I have met with many such cases. Women who are in the habit of passing these stones know what the symptoms are, and keep by them ready for the emergency a supply of remedies that have been found useful in assisting the passage of these gall stones, and who have become so used to these attacks that very frequently they do not even call in their medical attendant on every occasion they are attacked.

The necessity for operating in cases of gall stones is not only not 20 per cent. of the cases, but it is not even 1 per cent., and Kehr falls into the class of those surgeons I have elsewhere described as "often inexperienced in other safer and more rational methods of treatment." More than that, the mortality of 3.2 per cent. in operations for uncomplicated gall stones is quite excessive and unnecessary, as I am quite convinced that a patient, experienced physician would in a great number—practically the great majority—of these cases have been able to assist the stone to pass without the risk of any operation whatever.—I am, etc.,

Preston, Dec. 21st, 1908.

JAMES A. RIGBY.

THE TREATMENT OF SYPHILIS.

SIR,—Whilst agreeing generally with the view of Mr. E. Lane, as set forth in his excellent paper read before the Westminster Division of the Association, on the treatment of syphilis by intramuscular injections of mercury,¹ there are one or two points to which I take exception. As regards the preparation for injection Mr. Lane gives preference to calomel suspended in olive oil, with which one can only partially agree, for undoubted as the fact is that for removing any active signs of the disease no salt of

mercury comes up to calomel, still, that this removal is of a transitory nature when compared with the same result which is obtained by the employment of some of the other salts—such, for instance, as metallic mercury—this is not only my own experience, but also that of Fournier, vide the *Traité de la Syphilis*.

So convinced am I as to this that although I always now commence treatment with calomel injections, I limit these to a total of four when I continue treatment with injection of the metallic or salicylic salts.

Again, the preparation he recommends—calomel suspended in olive oil—is so painful that few if any patients would stand it for long. According to Fournier, this pain is in the majority intolerable, but luckily, about two years ago I hit on the idea of adding to the calomel preparation I use a combination of creosote and camphor, with a view to producing analgesia. This has proved quite a success, and now I am enabled to give calomel injections with more or less impunity.

There is one other point in Mr. Lane's paper with which I cannot agree. He advises that in carrying out treatment by intramuscular injections one of gr. $\frac{3}{4}$ of calomel be given once a week for a continuous period of between fifteen to sixteen weeks. Personally I would never sanction giving mercury for this prolonged period without a rest from all treatment, for long before the expiration of such a time the highest physiological effects of mercury would have been attained, and any further administration of it could only lead to disaster. Our practice in the army generally and at the Military Hospital, Rochester Row, when the intramuscular method is employed, is to begin with calomel injections, gr. $\frac{3}{4}$, once a week for four weeks, and then to substitute either metallic mercury or the salicylate salt of same to carry on treatment; the maximum number of injections given never exceed eight—more often six—and then a period of rest from all injections of two months is given. This period of rest is imperative, as the combination of injections and rest carries out what is now recognized by all as essential—"chronic intermittent treatment."—I am, etc.,

F. J. LAMBRIN,

Colonel, R.A.M.C.

London, W., Dec. 22nd, 1908.

THE OPERATIVE TREATMENT OF INTRAORAL CANCER.

SIR,—Mr. C. P. Childe, in his paper on this subject, discusses very fully and very ably many technical points on which there is still considerable diversity of practice. With most of his contentions I am in complete agreement, and I believe that surgeons who have most experience or this class of work approximate closely to the procedure he describes. There can be no difference of opinion as to the necessity of wide local removal of the primary disease, and none as to the necessity of complete removal of the whole glandular contents of the submaxillary triangle, and of the chain of glands along the great vessels down to the clavicle in every case. That the dissection of the neck should precede the removal of the primary growth will, I think, equally be agreed, for two reasons—first, in order that this dissection may be carried out aseptically; and, secondly, because many patients who have had the primary growth removed first cannot find courage to submit to a second operation. I assume that in the majority of cases the whole procedure is divided into two separate operations. I am sure that, in spite of some obvious advantages of removing both glands and growth at one operation, the balance of advantage is in favour of two operations.

It is possible in many cases to remove the glands without opening the mouth cavity and so infecting the wound. In these cases the neck wound heals *per primam*, and the second operation can be carried out at the end of six or seven days. Even where the neck wound must necessarily communicate with the oral cavity owing to the position of the growth to be removed, it is better to defer the removal of the latter until the neck wound has healed, or partially healed. I am aware that there is a risk of cancerous reinfection of the neck during the interval, and a risk of re-establishment of collateral circulation, and thus diminishing the advantages of ligaturing the lingual and facial arteries; but I have lost more than one promising case from exhaustion and shock when

¹ SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL, December 19th, 1906, p. 330.

I have been tempted to disregard this risk, and have completed the whole procedure in one operation.

There is another reason which weighs very strongly with me in this matter, and that is the importance of minimizing the interference with deglutition. In addition to removal of a part or whole of the tongue, there is interference with the action of the infrahyoid muscles, swallowing becomes still more difficult, and the danger of inhalation pneumonia thereby increased.

With what Mr. Childe says as to ligation of the lingual and facial arteries I am in entire agreement, and I have practised this as a routine procedure for many years. As the arteries are laid bare by the dissection of the glands it would be foolish not to take advantage of this circumstance, and the procedure is perfectly easy. Personally I always ligature both arteries close to their origin from the external carotid, where they can be found with ease and certainty.

With regard to the avoidance of laryngotomy, it is true, as Mr. Childe says, that preliminary ligation of these vessels makes removal of the corresponding half of the tongue a practically bloodless operation, and obviates the risk of inhalation of any serious quantity of blood. But even a small quantity of blood is apt to obscure the field at a time when a clear view is most necessary; for the precise and certain excision of the primary growth transcends in importance every other part of the operation.

For this reason I have lately employed a preliminary laryngotomy and plugging of the pharynx in almost all cases of removal of intraoral cancers. If the dissection of the neck has been carried out at a previous operation, as is my practice, there is no risk of neck infection from the small wound needed for the laryngotomy. I have found it an entirely harmless procedure, which makes an otherwise difficult intraoral operation quite simple. After the operation is completed the tube is withdrawn, the wound closed, and natural respiration restored.

Mr. Childe does not mention the use of the galvanocautery. I use this wherever possible for the removal of the primary growth, both as a precaution against local cancer infection and as a means of outlining the parts to be removed without hæmorrhage, and therefore with greater precision.—I am, etc.,

EDWARD DEANESLY, F.R.C.S.

Honorary Surgeon, Wolverhampton and Staffordshire
General Hospital.

Wolverhampton, Jan. 2nd.

THE TREATMENT OF FRACTURES OF THE BASE OF THE SKULL.

SIR.—In a paper of much practical value published in the BRITISH MEDICAL JOURNAL of December 26th, 1903, on the treatment of fractures of the base of the skull, by Dr. Maclaren, of Carlisle, a point is emphasized which must be regarded as of cardinal importance in the treatment of fractures of the cranial base attended with a discharge of blood or cerebro-spinal fluid from the ear.

In connexion with this subject I may be permitted to refer to a case which came under my care in Carlisle about thirty years ago. It was that of a boy who fell from a builder's platform placed at a considerable height on to the hard pavement of the street below. He was conveyed on a stretcher to his home about a quarter of a mile away, and when seen, within twenty minutes of the accident, was completely unconscious, convulsed, and had a discharge of blood and cerebro-spinal fluid from the ear.

An unusual feature presented by the case was a complete paralysis of the third cranial nerve, due to the accident, the resulting external strabismus being very pronounced. Acting upon Listerian principles to be observed in the treatment of a compound fracture, the head, which had been shaved for the application of an ice-cap, was cleansed, and the auditory meatus cleared out by means of wet carbolic wool rolled on the end of a probe. The meatus was then packed with cotton-wool wrung out of carbolic solution, and a pad of dry wool fixed over the side of the head. The dressings were changed frequently until discharge had ceased. The boy made a good recovery, and when seen some years after the accident there was nothing to indicate a previous head injury beyond the remains of the third nerve paralysis.

That the danger of septic meningitis in such cases was fully appreciated at any early period of antiseptic surgery

may be gathered from a sentence in Caird and Cathcart's *Surgical Handbook* (1889), where, under "Fractures of the Base of the Skull," it is pointed out that "in addition to general treatment an attempt should be made to combat septic meningitis by gently syringing the ear with 1 in 20 carbolic, dusting in iodoform, and plugging with antiseptic wool."

For obvious reasons the syringe, unless very carefully used, is objectionable.—I am, etc.,

Edinburgh, Dec. 28th, 1903.

WILLIAM BROWN.

THE ESTIMATION OF SUGAR.

SIR.—The interesting communication by Dr. Alexander Francis on hypotism in diabetes is illustrated by a table purporting to show the effect on the amount of sugar passed at different dates, and pains have been taken to estimate this quantity in grams per 100 c.cm., grains per fluid ounce and grains per pint, yet the absolutely essential information, namely, the total quantity of urine passed in twenty-four hours, is withheld. The need for knowing the total excretion of sugar if we are to estimate the gravity of a case or the effect of treatment has been repeatedly pointed out, but is apparently still ignored. It would not afford much information respecting B's income to know that he received 5 per cent. upon his invested capital, nor would it add much to be told that for every £1 he receives 1s. and for every five-pound note 5s. In addition to stating that a patient passes so many grains per ounce we should know how many ounces of urine are passed in order to calculate the quantity of sugar excretion *per diem*. A considerable difference in the percentage of sugar may occur without causing any alteration in the total amount. Some time ago a patient handed me a bundle of reports from the Clinical Research Association, each giving merely the number of grains per ounce, and I was struck by a remark of his wife, who said that she had not been able to notice any correspondence between the quantity of sugar as shown by the reports and the care with which he had been able to follow the rules of the diet that had been laid down for him. As this method is so misleading, I wrote to the Director of the Clinical Research Association and suggested that it would be well to notify subscribers of the importance, in estimating sugar, of getting at the total quantity passed in twenty-four hours, which can only be done where the amount of urine has been measured, and I am glad to say that my suggestion has been adopted.—I am, etc.,

Birmingham, Dec. 24th, 1903.

ROBERT SAUNDREY.

THE UNGODLY COUGH.

SIR.—Allow me to say a few words about the somewhat important subject, "The Ungodly Cough," as treated in the JOURNAL of November 28th. Some thirty or forty years ago I was in the habit of attending service at one or other of three churches here. Much coughing was present in all of them every winter. It used to make me angry, as I attributed it to disrespectful inattention of the congregation. At one of these churches some 180 Blue-coat boys attended. They used to cough incessantly, just like a pack of hounds finding "scent" again after a very brief check. For years past now no such distracting nuisance is to be found, but remarkable freedom from it. Why? Just because the buildings I speak of were heated with coke, the fumes of whose burning coming from the open gratings of the flues in the aisles tickled not, to be sure, the ears of the groundlings, but the fauces and epiglottides of those up in the galleries and on ground floor alike. Carbonic oxide was the transgressor. Wiser plans of heating have now been adopted. Coughing in packs and paroxysms no longer prevails, and the dear Blue-coat boys are as quiet as well-conducted mice. It is rather humiliating to think that neither doctors nor preachers suspected or investigated the cause of the nuisance alluded to, and my excuse for taking up the cause of "ungodly coughing" is because I fear that many country churches and chapels are still heated by coke.—I am etc.,

Stourbridge.

ALFRED FREER, M.R.C.S., L.S.A.

MEDICAL FEES.

SIR.—The article re "Medical Fees" in the JOURNAL of September 12th, 1903, p. 760, may well be noted by the profession.

In the first place, it is the first time in my memory that any public official has negatived the idea with which the public seems to be imbued, that a medical man should attend any and all cases whether he is to receive any fee or not. This is a departure of some importance, which may denote that a sense of justice is on the increase, or that the medical profession is becoming more powerful, and less inclined to be—to put it plainly—“cheated” without demur. In the second place, the criticisms as to the sending in of accounts yearly or half-yearly is one that might well be studied, as there is very little doubt that the profession as a whole has lost, and is losing, thousands by this method of procedure, coupled with the prevalent idea that a medical man will not sue for his fees. If accounts were sent monthly, or at latest quarterly, the profession would be so much to the good, especially if it were generally understood that defaulters would be “county courted” after, say, three months.

We live in a strictly business age, when even members of the aristocracy go on to the Stock Exchange and into trade generally, and as the general training of the community is commercial there is small respect or consideration for those who do not conduct their business affairs on business lines. When at Cambridge some three years ago I noted a letter in the local paper, stating that a Cambridge graduate in medicine might expect to make about £400 a year. This seems a very small sum to look forward to after a six or seven years' course and the outlay in money and work. Had the same amount of both been laid out in any other calling much better results would have been attained. Moreover, this is not the final outlay, as post-graduate study is required at intervals, and the constant supply of books and materials required makes a medical outfit more expensive than that of a cavalry officer, chargers and all.

If there is any need to harden the professional heart in regard to recovering their just dues, it is a study of the list of applicants for the British Medical Benevolent Fund, together with the reports of the financial condition of the various friendly societies, whose enormous reserve funds have practically been made out of what amounts to free medical attendance.—I am, etc.,

Ayr, North Queensland.

J. BOOTH-CLARKSON.

OLD AGE PENSION MEDICAL CERTIFICATES.

SIR,—The other day I received from the pension office of the district a batch of forms to be signed by me to the effect that the claimants were “permanently incapacitated through bodily infirmity from attending at the post office in person” to receive their pensions.

In the case of doctors situated in remote highland and island parishes this work in some cases means many miles of travelling. To whom are we to look for payment for these certificates? Would it be “infra dig.” for us to ask it from the “aged veterans of labour”? It is not “infra dig.” for postmasters to receive the sum of one shilling sterling for “filling in their papers.”

Claimants for a pension get all their other certificates free, and I notice, in reading through the Act, that in the case of all other officials who are required to do clerical or other work in connexion with this huge scheme of national pauperism provision is made for their remuneration. I have looked in vain, however, for some such clause as the following:

In the case of any old age pensioner who is permanently incapacitated through bodily infirmity from attending at a post office in person, he (or she) shall produce a medical certificate to that effect, which medical certificate the doctor shall grant free of charge.

I think the British Medical Association should draw the attention of Parliament to the omission of such a clause, in case any medical man might so far forget himself as to think he was entitled to some remuneration for granting the certificates to which I have alluded.—I am, etc.,

Shetland, Dec. 19th, 1923.

HENRY PEARSON TAYLOR.

THE EXAMINATION AND CERTIFICATION OF MENTAL PATIENTS.

SIR,—I have read Dr. James Neil's paper on the examination and certification of mental patients, in the BRITISH MEDICAL JOURNAL of October 24th, and also Dr. Cockle's

letter on the subject in the issue of November 23th, with the greatest interest.

When a member of the medical profession is asked to see an alleged lunatic it is surely his duty to make a careful examination of the patient with a view to giving advice as to treatment, and not merely to endeavour to obtain evidence upon which to base a certificate of insanity.

The all-important point that the physician has to decide is, whether the patient should be placed under control or not. The relatives, as is only natural, are usually most anxious to avoid certification, and the medical man is reluctant to urge it unless it is absolutely necessary. Insanity is a disease, and, as in all other disorders, the primary aim and object of the physician must be to obtain the best possible treatment for his patient. This in many cases can only be secured in an institution, the restraint being regarded as a part of the treatment.

Should the physician conclude from examination of the patient and information received from the friends that the patient ought to be placed under care, steps must be taken to accomplish this legally. The law requires the medical practitioner first to certify that the patient is of unsound mind and a proper person to be detained under care and treatment, and secondly to state his reasons for arriving at this conclusion.

The facts indicating insanity observed at the time of examination have to be such as will carry conviction to the mind of a layman that the patient is *non compos mentis*. In many instances facts of this character can be readily set down; but in others, though the certifying medical man may be absolutely certain that the patient ought to be placed under care, they are difficult to adduce. It is in this latter class of cases that perseverance and tact are required, and that every effort must be made to obtain material for a satisfactory certificate. Such patients often suspect the medical man, and are consequently very much on their guard in his presence, which enhances the difficulties of the situation. The existence of delusions is commonly considered, by lawyers at any rate, conclusive evidence of insanity, and hence endeavours are made to ascertain if the patient entertains any such, for the purpose of certification. Many people, however, now at large have delusions, and could very possibly be certified in consequence; but this is not done, and rightly so, because their conduct is not sufficiently affected to justify such a step. It is the conduct of the patient that determines the physician's action.

Two patients may hold precisely similar delusions. In one case it may be the duty of the medical man to make use of these delusions to certify the patient, whereas in the other such a course may be absolutely unnecessary.

If a patient is willing to enter an institution as a voluntary boarder, the necessity for immediate certification disappears. This arrangement unfortunately is only possible in the case of patients with private means, as voluntary boarders are not admitted into county asylums. The only alternative to certification for patients unable to pay is a period of probation in the workhouse infirmary.

In conclusion, the idea still unfortunately seems to be prevalent that if a medical man who has made a special study of insanity be called to see a patient he will immediately desire to certify him and have him removed to an asylum. This idea is both mischievous and erroneous and needs correction.—I am, etc.,

Usbridge.

RALPH BROWN, M.B.Lond.

THE LIMITATIONS OF A PURIN-FREE DIET.

SIR,—The purin-free diet, like many another special mode of living, owes its success to the fact that it undoubtedly suits some people remarkably well. That seems to be the best argument against its being universally suitable that we can get. Scarcely two people in any dozen, or perhaps more, whom we meet have similar food tastes or metabolic powers, and it is the little differences which count in ordering a patient's diet.

Some persons seem to have an abnormally sensitive intrahepatic circulation, quite apart from their general circulation. They are often active and nervo-sanguine, or gouty. With such persons an ounce more flesh protein than their usual amount, or a dessertspoonful of alcohol, or a little more exercise or excitement or mental study than usual, will cause hyperaemia of the liver, which produces extreme mental and physical depression. Such subjects

find their greatest safeguard of health in an almost purin-free diet. Their livers seem to act as blood reservoirs which are easily filled, and no doubt part of their languor and irritability is due to actual cerebral arterial anaemia when the reservoir is full. Very often such patients terminate the first ten days or so of a purin-free diet in an explosive bilious attack due to the suddenly lessened intrasplenic blood pressure, and with that in their minds terminate also their attempts at a continuance of their treatment. But if they persist in their attempts, after treating by blue pill, etc., the bilious condition, they do well; and it is an interesting fact that, as was lately pointed out in your correspondence, on returning to purins they find they have acquired greater tolerance for them for some considerable time.—I am, etc.,

C. W. LAWSON, M.A., L.R.C.P.S.

Rothbury, Dec. 18th, 1908.

SIR,—I glean from the last paragraph of Dr. Bryce's letter in the JOURNAL of December 12th, p. 1781, that he thinks that I have not watched my cases for a sufficient length of time to appraise the purin-free diet. May I be allowed to mention that during the last five years I have had the opportunity of watching numerous patients who have lived on the diet, for periods varying from a few months to fifteen or more years, and through my position as medical officer to a purin-free diet home, where patients are received for practical instruction in the diet, I think that I can claim a unique experience.

It is unnecessary for me to enlarge upon the superiority of a fleshless diet in athletes. The remarkable records of strength and endurance furnished by flesh abstainers have been sufficiently published.

I quite agree that the purin-free diet has its limitations. Nobody realizes that more than I do. I have been compelled to abandon it myself. But my experience of its effects will not permit me to accept Dr. Bryce's limitations.—I am, etc.,

Slough, Dec. 14th, 1908.

W. L. BOWEN DAVIES.

SIR,—My long practical experience leads me to endorse Dr. Alexander Bryce's opinions as expressed in his letter in the JOURNAL of December 12th, 1908. I have experimented upon myself with a purin-free diet with every care, and found it infinite inferior to my limited mixed diet treatment. I have also given it to patients with no better results. On the other hand, patients who have come to me and who have been on a strict purin-free diet, have greatly benefited by a carefully regulated purin and anti-purin diet. Experience has taught me, it is not so much the composition of the food eaten but the quantity which is of the utmost importance in cases of indigestion, gout, rheumatism, and many other diseases. The patient should only be allowed a mixed diet in small quantities, so that there is a distinct hunger for every meal allowed. The food should be very nutritious and of a good quality, in order that waste and faecal material is reduced as much as possible, whereby fermentation is lessened and freedom from auto-intoxication assured. A diet of this kind, with a regular action of the bowels, is all that is required to obtain the very best results of treatment by diet. The food faddists, who have grown so numerous of late years, are certainly to be condemned on general medical lines.—I am, etc.,

London, W., Jan 4th.

THOMAS DUTTON.

SIR,—Permit me to crave your kind indulgence for another letter on this subject, with especial reference to one or two statements in Dr. Haig's letter in the BRITISH MEDICAL JOURNAL of December 26th, 1908.

He appears to take it for granted, or that it is an established fact, that the healthy have no difficulty in not only subsisting on a purin-free diet, but in maintaining or even improving upon their health and vigour of constitution, if this be possible. He admits that the unhealthy may have some difficulty in tolerating the diet, but after a "considerable preliminary treatment" this disability is easily removed. That this is not the opinion of even his enthu-

siastic followers is evident from the letter of Dr. Bowen-Davies, who has "seen cases that cannot be put upon a purin-free diet, through inability to digest it."

Dr. Haig states that one cause of my bad results with this diet is patent because my patients failed to digest both proteids and carbohydrates. Now, he must surely have forgotten or failed to refer to my original paper, in which I clearly demonstrated that patients who could at the time of the institution of the purin-free diet digest all kinds of food without difficulty, were compelled after a variable time, never less than nine months, to relinquish the diet, however unwillingly, because of the accession of anaemia, diminished vigour and vitality, nasal catarrh, rheumatism, etc., and a recurrence of the chronic malady for which the diet had been prescribed, and which as a rule at first had been greatly relieved. In a previous letter Dr. Haig suggested that I had obtained those bad results because of a deliberate or unintentional diminution of proteid in the dietary. In my reply I dissipated this idea, contending that in each case the amount was carefully calculated according to his rules, but at the same time stating my belief that the damage was brought about because much of the proteid and carbohydrate they ingested failed to be digested, and remained in the colon undergoing putrefaction with consequent auto-intoxication. But this condition had not necessarily existed before they commenced a purin-free diet, and for a considerable length of time thereafter certainly did not exist, but only became evident when their vitality and powers of digestion had been weakened by a diet which, though theoretically efficient, was practically inefficient for their bodily needs. I have no hesitation in saying that the patients lost vigour as a result of their adoption of the purin-free diet under perfect conditions for testing it, and I have been greatly interested to find that since my paper was written and without any suggestion from me, my staunchest purin-free patient has quietly dropped her fleshless diet because she cannot retain her vigour upon it, even although she knows from experience she is thereby risking an attack of epilepsy.

He appears to think also that I have overlooked the fact "that there never need be more carbohydrate in a purin-free diet than in that in ordinary use." This is in reference to my own experience to cure colitis. I wonder if he will be surprised to know that I have a patient and friend who developed colitis on a purin-free diet which in my opinion contained too much carbohydrate and who is now, and has been for several years, subsisting with comfort on a vegetarian diet which contains a minimum of carbohydrate, but is by no means purin-free.

I am quite at one with Dr. Haig that excess of free purins is conducive to disease rather than to health, doubtless because of their stimulating peptogenic properties, which tend to an excessive ingestion of proteid foods, but I cannot see any reason why the bound purins in the small quantity in which they are found in our accustomed flesh foods, evidently so essential to maintain health and vigour in most people, should damage any but the most sensitive organisms, and such, of course, must be the exception.

Far be it from me to disallow the advantages of science as applied to diet, but I can hardly think that Nature should be so negligent of her duties as to compel humanity to await the results of scientific investigation on a matter so vital to its existence. Her methods of working are far different from that.

I see no reason to abandon my contention that however valuable as a method of treatment, the purin-free diet is not suited as a dietary for the ordinary purposes of nutrition in every-day life.—I am, etc.,

Birmingham, Dec. 29th, 1908.

Medico-Legal.

POISONING BY FERRO-SILICON.

AN inquiry was concluded in Grimsby on December 21st, 1908, into the circumstances attending the death of five Jewish emigrants during the short sea transit between Antwerp and Grimsby. Their illness was so sudden and death so rapid that it was at first supposed that cholera might have been the cause, and appropriate measures were taken. Ptomaine poisoning was next suggested, but finally the deaths were traced to inhalation of the fumes from nine tons of ferro-silicon which the ship was carrying. This was stowed in thirty-five casks in a hold just below the cabin in which these emigrants were quartered, and on the day on which they fell ill all portholes and doors had been kept closed owing to bad weather. Evidence was given by Dr. Simpson, Medical Officer of Health for Grimsby, to the effect that *post-mortem* examination revealed symptoms indicative of death through inhalation of a poisonous gas, but no evidence of ptomaine poisoning or of any infective disease. The borough analyst said that ferro-silicon was used by steel makers and regularly imported from Belgium. It contained arsenic and phosphorus and was more liable to be affected by sea air than by land air; persons poisoned by fumes from it exhibited great thirst. On behalf of the Great Central Railway Company, to whom the ship belonged, it was stated that cargoes of ferro-silicon had been carried for many years without mishap, but some time ago it had been decided to refuse all such cargo. Acceptance of the present consignment was due to an assurance from the German manufacturers that the ferro-silicon was now manufactured by a process which eliminated all dangerous characteristics from the compound.

VALUE OF A PRACTICE.

VENDOR.—Such a practice would probably be worth from one to one and a half years' purchase.

MEDICAL ATTENDANCE ON HOTEL VISITORS.

J. B. wishes to know whether the proprietor of an hotel is not responsible for the fee if he sends for a medical man to attend to a patient staying at his hotel.

* * * When an hotel keeper sends for a doctor to attend to someone taken ill at his hotel, it is presumed that he is acting as agent for that person, who is alone responsible for the doctor's fees. It would be unreasonable to suppose that an hotel keeper intended to pay the medical expenses of a stranger staying at his hotel, and before the doctor could charge him personally he would have to get a written undertaking from him to be responsible for the medical expenses if they could not be recovered from the patient.

REMOVAL OF LUNATIC.

F. H. G.—The medical man appears to us to have just grounds for complaint on account of the discrepancy between the opinion and directions of the official with whom he communicated by telephone and the statements and action of the relieving officer, more particularly as he was put thereby to considerable and unnecessary trouble. We should be glad to know what reply is received from the Asylums Committee, and the reason for refusing to return the unused certificates. In the meantime, however, we may point out that even under a summary reception order (as provided for in Section 13) this patient would probably have been sent to a workhouse pending removal to the asylum; and also that, inasmuch as the patient in question belonged, presumably, to the "pauper" class—that is, he was "in such circumstances as to require relief for his proper care"—his certification and disposal would be decided most properly by the parochial authorities.

LONG CYCLING ROUNDS.

EIGHT YEARS AN ASSISTANT asks: (1) Can an assistant be reasonably expected to cycle a round of ten or fifteen miles in the rain, on heavy roads, in an exceedingly hilly country district, and this on several days a week throughout the winter? (2) Is a principal bound to provide means of conveyance for an assistant over long distances?

* * * (1) A principal usually expects an assistant to do what he is in the habit of doing himself. If the round complained of is one that the principal would do himself, if he were without an assistant, there would appear to be nothing unreasonable in the latter being expected to do it. It is presumed that both principal and assistant are fairly good cyclists, and that the latter was informed at the time of his engagement that much of the work would have to be done on a bicycle. (2) Not if the distance could be reasonably done on a bicycle. In all these cases the principal must decide as to what is reasonable and what is not. If the assistant disagrees with him, he has only one remedy, and that is to terminate his engagement.

THE TITLE OF M.D.

M.D.BRUX. inquires whether it is the "correct thing" for a medical practitioner to put "M.D. M.R.C.S." when the "M.D." is that given by the University of Brussels.

* * * This has always been a point of contention in the profession, but in the light of modern decisions it would appear that there is nothing illegal in such a practice. The only instance in which this point has come before the law courts without complications was in *Ellis v. Kelly* (30 L.J., 35), where a practitioner was prosecuted for calling himself "M.D." on the strength of possessing the M.D. Erlangen, being at the same time a registered practitioner with the M.R.C.S., L.S.A. Eng. The bench of magistrates before whom the case first came refused to convict, and, on appeal, the Divisional Court upheld their decision. There are abundant precedents for the practice among men of high standing as may be seen by looking through the *Medical Directory*.

AGREEMENT TO PURCHASE A PRACTICE.

MUTANS asks for information regarding the following points as to the purchase of a practice (death vacancy): (1) Does the vendor bear the cost of the agreement and a copy for the purchaser, or is the cost shared equally? (2) On drawing up a legal agreement, what stamp duty is required? (3) When book debts are included in the purchase, if the purchaser does not sign the agreement till a fortnight after the death, nor assume charge of the practice for three weeks, a locum-tenent of the vendor being in charge in the meanwhile, can book debts be collected in the interval by the vendor, or must outstanding debts at the death be left and turned over to the purchaser? (4) To whom belong the earnings of the locum-tenent in the interval?

* * * (1) The purchaser pays all the costs of the assignment of the practice, unless otherwise agreed, and in everything else the expenses are either shared between the parties equally or each pays his own costs. (2) This depends on whether there is a monetary consideration in the agreement or not. If not, a sixpenny stamp is all that is required; but if there is a pecuniary consideration the stamp must be *ad valorem*—that is, it will vary according to the amount of such consideration. (3) (4) All these points depend on the wording of the agreement, and the date of the signature is immaterial. It should be clearly stated in the agreement whether the purchaser takes the practice from the death of his predecessor or from the date of signing the agreement. The answer to the points raised will depend entirely on what was agreed to in this respect.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

DUTIES OF CERTIFYING FACTORY SURGEONS.

PRIVATE.—In the instructions issued by the Secretary of State to certifying factory surgeons it is stated that "the duty assigned to the certifying surgeon in respect to an accident will not authorize any interference with the medical or surgical treatment of the person injured." It is not uncommon, however, for the factory surgeon to fill other duties at a works, for which he gets separately remunerated, and it appears possible that some such arrangement might have been the reason for the action of the particular factory surgeon alluded to. Our correspondent should ascertain in what capacity the certifying surgeon acted.

CERTIFICATES FOR INSURANCE PATIENTS.

POLICE writes that he attended a poor patient with cancer for some months and has since been asked by a relative who insured the deceased to inform the insurance company how long the patient had been ill. This he declined to do on the ground that no medical examination having been made he thought the insurance company should pay for the information. He asks for advice as to the proper course to pursue with due consideration for the interests of the relatives who he believes have acted in good faith. The parties concerned are very poor, and unable to pay any adequate fee for a certificate.

* * * It is true that some industrial insurance companies take no precautions to ascertain that the person is in good health when insured and accept policies through their agents, which are illegal on account of the absence of "insurable interest," but if they will not pay the claim without obtaining certain information, the medical attendant must remember that if he refuses to give it to a duly authorized person, the family and not the company suffer.

THE RELATION OF MEDICAL PRACTITIONERS TO ADVERTISING INSTITUTIONS.

Z. asks: What is the exact medico-ethical position of: (1) A practitioner who holds the post of consulting physician to an institution which advertises cures by light or radiant heat? (2) The consultant to establishments for the cure of obesity, intemperance, morphinism, etc.? (3) To those employed as medical advisers by patent medicine vendors?

* * No general rule can be laid down with regard to the first and second queries except that the advertising should be confined to the medical press or to circulars in prospectuses sent to the medical profession. With regard to the third question, in our opinion a medical practitioner who accepts such a position must be indifferent to any consideration of medical ethics.

MEDICAL ADVERTISING.

A CORRESPONDENT sends us a handbill and a small poster advertising a smoking concert to be held by the "Victoria Cross Tradesmen's Society," which is apparently a provident institution to provide medical attendance, sick pay, and life insurance "for the small cost of 4s., or less than a penny a week," and the medical adviser's name is printed on both.

* * This is on all fours with a case brought before the General Medical Council in November, 1900 (Minutes of the General Medical Council, vol. xxxvii, p. 119, which ended by the defendant severing his connexion with the institution. It ought to be generally known that such advertisements of clubs and benefit societies are not permitted.

CANVASSING.

QUERO writes: "A. B. having taken a house in an outlying part of a town where resident doctors are scarce and the population poor, has employed a man to canvass for him to get members of a weekly payment medical club. The canvasser has instructions not to canvass persons who are in a similar club belonging to X. Y. who lives at a distance, but keeps a resident assistant in the neighbourhood where A. B. lives. Is A. B. acting in any way unprofessionally, or so as to exclude him from membership of the British Medical Association?"

* * Canvassing is distinctly contrary to the resolution of the General Medical Council dated December 1st, 1905, by which the profession were warned that canvassing renders the practitioner resorting to it liable to be charged with infamous conduct in a professional respect, and we think that it would be a bar to membership of the British Medical Association if the facts were brought to the notice of the body asked to elect.

PROFESSIONAL SECRECY.

H. A. L. writes: "A. is consulted by B., a nurse who has acquired the morphia habit. B. is a member of a nursing organization but is not at present on duty. She is anxious to break off the habit, but will not consent to the secret being divulged. What is A.'s duty—(1) respecting the secret; (2) respecting the treatment; (3) respecting B.'s work?"

* * (1) It does not appear in any way to be A.'s duty to violate the established rule of professional secrecy. (2) He should carry out the treatment to the best of his ability. (3) He should advise B. to give up her work while under treatment as it is difficult to believe that it would be successful unless she were under control.

GRATUITOUS ATTENDANCE ON DOCTORS.

H. C. M. (Jersey) writes: "Perhaps you may be willing to allow me a few lines in relation to the matter under the above heading in the BRITISH MEDICAL JOURNAL of December 25th, 1908. I have, indeed, no desire or intention to discuss the principles involved, especially having regard to the fact that the views expressed editorially in the JOURNAL upon so many occasions, in response to appeals, have been, I think, we should all consider eminently reasonable, as well as fair and just to all concerned. Also because, with some knowledge of our profession to guide me, I venture to hold that, among our many failings, want of generosity towards each other in sickness or accident is not one that can with justice be brought against us. I think, however, it may not be without interest to recall how a celebrated physician of the past—I believe Dr. William Abercrombie—acted upon an occasion in which, as he considered, no doubt or difficulty arose upon the question of fee. The little incident was one which that good man and excellent practitioner of the old school, the late Dr. William Dumbreck, of Edinburgh, was fond of narrating to his pupils. It appeared that Dr. Dumbreck, early in his career, had occasion to consult Dr. Abercrombie about himself, and at the conclusion of the consultation ventured, though with some diffidence, to suggest a fee. Said the great man, turning upon his young confère with kindly indignation, "What, sir! What, sir! offer me a fee! Do you think me a cannibal, preying upon my own flesh and blood! Do you think me a cannibal?"

THE ARMS OF THE UNIVERSITY OF EDINBURGH.

M. I.—Stationery bearing the arms of the university is commonly sold in Edinburgh for the use of students, and by no means implies that the user is a graduate. There is, however, a distinction between the use of it in Edinburgh and elsewhere, especially in the case of a non-graduate, but it is possible that in this case the individual is merely using what is left of a supply purchased in Scotland.

Universities and Colleges.

UNIVERSITY OF OXFORD.

The following degrees have been conferred in Medicine and Science:

D.M.—H. W. Kave, Magdalen.

D.Sc.—H. L. Bowdler, New.

B.M., B.Ch.—M. Davidson, Trinity; H. E. Gibson, Queen's; G. D. H. Carpenter, non-collegiate; J. F. Horsey, Wadham; H. M. C. Green, Wadham; O. L. V. de Wesselow, Corpus Christi.

D.Sc.—M. Spote, non-collegiate; H. E. Cockesedge, Keble.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on December 16th, 1908.

Recognition of Teachers.

The following were among those recognized as teachers of the university in the subjects and schools indicated:

King's College.—Dr. St. Clair Thomson (Laryngology).

Middlesex Hospital.—Dr. Victor Bonney (Midwifery and Diseases of Women); Dr. John Cameron (Anatomy); London School of Medicine for Women.—Dr. E. F. Buzzard (Pathology); Miss Mabel E. Gates (Anaesthetics); Dr. T. B. Hyslop (Mental Diseases); Mrs. Florence E. Willey (Midwifery and Diseases of Women).

St. George's Hospital.—Mr. Thomas S. Kerr (Tropical Medicine).

London Hospital.—Dr. Wilfred J. Hadley (Medicine); Mr. Jonathan Hutchinson (Surgery); Dr. Wm. Wright (Anatomy).

St. Mary's Hospital.—Mr. C. Irving Graham (Laryngology); Dr. G. William Hill (Laryngology).

National Hospital for the Paralyzed and Epileptic.—Mr. T. Grainger Stewart (Clinical Medicine).

Registration of Internal Students.

It was resolved that the following be added to the end of the note on page 3 of the Red Book, September, 1908:

Students whose names have been returned by the authorities of a school or institution as having discontinued attendance at an approved course of study and whose names have consequently been removed from the register of internal students may be re-registered, after notification by the authorities of a school or institution that they have resumed an approved course of study. Fees payable in respect of late applications for re-registration will be on the same scale as those payable in respect of late applications for registration.

Regulations as to Approved Courses of Study.

It was resolved that Section 12 of the General Regulations as to approved courses of study (Red Book, September, 1908, p. 7) be amended to read as follows:

A student's attendance at an instruction course as prescribed under Regulation 6 may be exceptionally relaxed with the approval of the Academic Council and of the school or institution to which he is attached, provided that (a) his attendance for the whole course of study does not fall below the minimum prescribed in the schedule to these regulations, if any, and (b) his attendance at the instruction course, though not satisfying the requirements contained in Regulation 5, is in the opinion of the certifying authority sufficient for the student in question. Applications for exemption under this regulation must be made not later than the end of the first term of the session in respect of which such exemption is desired.

(The amendment consists in the words printed in italics.)

Regulation for the B.Sc. (Honours) Degree for Internal Students.

It was resolved that the following be inserted in the regulations for internal students after the fifth paragraph under the heading "B.Sc. (Honours) Degree" (Red Book, September, 1908, p. 198), and after the second paragraph on page 64:

Students who have taken the B.A. (Honours) degree in mathematics as internal students, and have passed the Intermediate Examination in Science for internal students, will not be required to pursue any further approved course of study before being admitted to the B.Sc. (Honours) Examination in mathematics as internal students.

Regulations for the Matriculation Examination.

It was resolved that the regulations for the Matriculation Examination be amended in the following particulars (Calendar, 1908-9):

(a) Page 241, line 1, omit the words "from the list."

(b) Page 241, omit the starred languages.

* Application made in view of change of status of applicant.

(c) Page 241, after the words "elementary biology-zoology" insert the following:

A candidate desirous of offering any language or languages other than those named above should submit his proposal for the consideration of the Matriculation Board. The normal notice of such proposal is six months before the beginning of the matriculation examination for which he enters. Candidates giving less than six months' notice are advised that it may not be possible to make arrangements for papers to be set at the next matriculation examination even though the language be approved.

Proposals to take a particular language, other than those mentioned above, must be accompanied by a special fee, additional to the regular matriculation fee of £2. This fee will be returned should the proposed language not be accepted by the Matriculation Board, but in no other case. The amount of this additional fee varies with the language selected, and can be ascertained on application to the External Registrar.

(d) Pages 243-4 omit the syllabuses of the examination in Spanish, Portuguese, Italian, Modern Dutch, Arabic, Hebrew, Sanskrit, and Chinese.

Military Education Committee.

A committee was appointed to control, under the direction of the Senate and in accordance with the War Office Regulations, the university contingent of the Officers' Training Corps.

Appointments.

Sir William Collins, M.D. M.S., M.P., was appointed a member of the University College Committee for the remainder of the period 1903-9, vice Dr. S. Russell Wells, resigned.

Dr. Frederick Taylor was appointed a member of the council for external students for the remainder of the period 1903-9, vice Mr. Mackinder, M.A., resigned.

Sir William L. Alcock was reappointed a governor of the Maidstone Grammar School.

The Senate have, at the request of the Kent Education Committee, nominated Dr. W. B. Warle (Tunbridge Wells and Southborough) a member of the local Higher Education Subcommittee.

Gilchrist Studentship for Women.

The Gilchrist studentship of £100 tenable for one year by a graduate of the university who is prepared to take a course of study in an approved institution in preparation for some profession, will shortly be awarded. Applications must reach the Principal not later than February 28th, 1909.

Advanced Lectures in Physiology.

The following courses of advanced lectures in physiology will be delivered during the second term:

1. Eight lectures on the chemistry of food by S. B. Schryver, D.Sc., Ph.D., at University College on Fridays at 5 p.m., commencing on January 22nd.

2. Four lectures on some practical methods employed in physiological chemistry by R. H. A. Plimmer, D.Sc., at University College on Wednesdays at 5 p.m., beginning on February 5th.

3. Two lectures on the evolution of function in the human brain in relation to structure by Dr. F. W. Mott, F.R.S., at King's College on Mondays at 4.30 p.m., beginning on February 8th.

4. Eight lectures on the regulation of body temperature by Dr. M. S. Pembrey, M.A., at Guy's Hospital Medical School on Thursdays at 4 p.m., beginning on January 14th.

5. Eight lectures on prophylaxis against infection by Dr. W. Bulloch at the London Hospital Medical College on Fridays at 4.30 p.m., beginning on January 15th.

Courses 1, 4, and 5 have been recognized by the Senate as courses of advanced lectures which a candidate at the B.Sc. (Honours) examination in physiology may name for part of his practical examination.

The course of four lectures on the secretion of urine by Professor T. G. Brodie, M.D., F.R.S., originally announced for the second term, has been postponed to the third term, and will be given at King's College on Mondays at 4 p.m., beginning on June 7th.

Advanced Lectures in Zoology.

The following courses of advanced lectures in zoology have been arranged for the second term:

1. Three lectures on the anatomy and zoological relation of the antrophony species by Dr. Arthur Keith, to be given in the theatre of the Royal College of Surgeons, Lincoln's Inn Fields, on January 15th, 21st, and 29th, at 5 p.m.

2. Two lectures on problems of lake fauna, with special reference to the lakes of Africa, by Dr. W. A. Cunningham, B.A., Ph.D.; details of time and place to be announced later.

The lectures are addressed to advanced students of the university and others interested in the subjects dealt with; admission free without tickets.

Chadwick Lectures on Hygiene and Municipal Engineering.

Dr. Louis C. Parkes will deliver at University College the courses of three Chadwick lectures on the medical aspects of recent advances in hygiene as connected with sewerage on Tuesdays at 4 p.m., beginning on February 2nd.

UNIVERSITY OF EDINBURGH.

ANNUAL REPORT FOR 1908.

Number of Students.

DURING the past year the total number of matriculated students (including 595 women) was 3,323, being 48 more than the number for last year, and the highest number reached for seventeen years. Of these 1,156 (including 505 women) were enrolled in the Faculty of Arts, 295 (including 16 women) in the Faculty of Science, and 1,490 (including 59 women) in the Faculty of Medicine. Of the students of medicine, 667, or nearly 45 per cent., belonged to Scotland; 281, or 19 per cent., were from England and Wales; 132 from Ireland; 76 from India; 306, or about 20 per cent., from British colonies; and 28 from foreign countries. These figures show that the proportion of non-Scottish students of medicine is well maintained; and it is worthy of note that the number of Colonial students exceeds by 34 the highest number reached at any time during the last twenty years.

Degrees Conferred.

The following degrees were conferred during 1908: Master of Arts (M.A.), 182 (including 92 women); Bachelor of Science (B.Sc.), 47 (including 4 women); Doctor of Science (D.Sc.), 4; Bachelor of Medicine and Master in Surgery (M.B., C.M.), 4; Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), 184 (including 19 women); Doctor of Medicine (M.D.), 76 (including 3 women).

The General Council of the University now numbers 10,579.

Fellowships, etc.

The total annual value of the University Fellowships, scholarships, bursaries, and prizes now amounts to about £18,650—namely, in the Faculty of Arts, £11,045; in the Faculty of Science, £1,545; and in the Faculty of Medicine, £3,730. A number of bursaries are in the gift of private patrons, but the great majority of the university bursaries, prizes, etc., are awarded by the Senatus after competitive examination. In addition to the above, a sum of upwards of £660, being the income of the Earl of Moray Endowment Fund, is annually available for the encouragement of original research.

Lectureships, New Courses, etc.

New lectureships have been instituted by the University Court as follows: Mr. R. Stewart MacDougall has been appointed Lecturer in Botany, to give courses of instruction in that subject to men and women students of arts and science. Mr. J. P. Mackenzie, D.Sc., has been appointed to deliver a course of lectures on chemistry to women students in the faculties of arts and science; while Mr. A. C. Cumming, D.Sc., has also become a lecturer in the department of chemistry. The University Court has instituted a lectureship in the history of medicine, and Mr. J. D. Comrie, M.A., B.Sc., M.D., who has been appointed lecturer, is expected to deliver part of the first course before the opening of the present winter session, and the remainder in the summer session. Mr. G. M. Kinnear has been appointed joint lecturer with Dr. T. S. Clouston in mental diseases. Lastly, Messrs. J. M. Cotterill, M.B., C.M., F.R.C.S.E., and J. W. B. Holdson, M.D., F.R.C.S.E., have been appointed Lecturers on Clinical Surgery.

Early in the year several special short courses of lectures were given—one on Sugars; another on The Synthetic Dye Stuff; by Dr. J. E. Mackenzie; Heredity, by Dr. F. H. A. Marshall; Protein Metabolism, by Dr. W. Cramer; Chemistry of Colloids, by Dr. W. W. Taylor; Physiological Aspects of Immunity Problems, by Dr. James Ritchie; Sensory Conduction in Cord, by Dr. Sutherland Simpson.

Personal Changes.

The vacancy caused by the death of Professor Annandale in December, 1907, was filled in June by the appointment of Mr. Francis M. Caird, M.B., C.M., as Regius Professor of Clinical Surgery. At the close of the summer session Professor Cram Brown, then the senior member of the professoriate, resigned the Chair of Chemistry, and was succeeded by Mr. James Walker, D.Sc., Ph.D., formerly Professor of Chemistry in University College, Dundee. Numerous changes in the staff of lecturers, in addition to those already noted, have occurred. Mr. J. W. Bews, M.A., B.Sc., has been appointed lecturer on plant physiology, in room of Dr. A. W. Borthwick. Dr. Harold Pringle succeeds Dr. P. T. Herring, and Mr. W. A. Jolly, M.B., Dr. Sutherland Simpson, as lecturers on histology and experimental physiology respectively. Dr. G. H. Melville Dunlop is successor to Dr. T. M. Burn Murdoch in the lectureship on diseases of children; Major D. G. Marshall, M.B., F.R.S., succeeds Brigade Surgeon Lieutenant Colonel James Arnott as lecturer on diseases of tropical climates; and Dr. Alexander James, Dr. J. O. Affleck, as lecturer on infective fevers.

Structural Changes.

Further progress has been made in adapting to other purposes the rooms in the old buildings vacated by the Natural Philosophy and Engineering Departments on their removal to the new laboratories in Infirmary Street. The upper floor of the old Natural Philosophy Department has, by the elevation of the roof, afforded three good class-rooms, and a women students' reading-room, for the joint use of the Mathematics and Geography Department, and also for teaching military subjects. A handsome room, long used in connection with the Zoology Department, has been adapted as a meeting room, much-felt want by providing a second examination room. An additional room in the new Natural Philosophy building has also

been obtained for the practical training of teachers in Physics. The Dunlop Scholarship Fund has increased so as to permit of the institution of an additional scholarship in the faculty of medicine. There are now twenty-four scholarships in all on this foundation, each of the annual value of about £100.

Additions to the Library.

Additions to the University library for 1908 numbered 5,182.

Benefactions, etc.

By the scheme of allocation lately intimated by the Carnegie Trust for the second quinquennial period provision is made towards certain of the needs of the university, especially in regard to the endowment of lectureships, the purchase of books for the library, buildings, permanent equipment, and apparatus. The Right Hon. William McEwan, LL.D., has given a sum of £5,450 as an endowment for the expenses of upkeep of the McEwan Hall. A grant of £400 has been made by the Combe Trustees, in addition to sums already given, for the purchase of apparatus in connexion with the George Combe Lectureship in General and Experimental Psychology.

Faculty of Medicine.

Several important changes have been made in connexion with the new regulations for graduation in medicine and surgery, which were passed in 1907. The classes in the Faculty of Medicine now open at the beginning of October, instead of, as formerly, about the middle of that month; degree examinations in all the subjects now take place in December; and a graduation ceremonial will be held before Christmas. Accommodation was again given in September, for a scheme of post-graduate courses in medicine, held under the joint auspices of the university and the Royal College of Physicians and Surgeons, and both of these schemes proved highly successful.

DEGREES.

THE following degrees were conferred on December 19th, 1908:

M.B., CH.B.—Girdhari Lal Batra, H. Blyth, J. Brander, J. A. Browne, F.A.; H. B. Caldwell, J. A. B. Carroll, G. H. Lart, Margaret Davidson, J. T. Dickson, W. J. Duncan, W. G. Evans, Helen Forbes, P. J. E. Garvey, H. R. B. Gibson, A. B. Gordon, W. B. Grant, G. R. Gray, R. D. L. Greene, J. A. V. Hackett, J. K. Hamilton, M.A., St. G. M. L. Homan, H. Hutson, W. P. S. Johnson, E. W. Kirk, F. R. Leake, J. Lambell, C. L. Laurent, J. S. Leavack, N. F. Lloyd, C. L. Lowe, Margaret McEwan, J. V. MacDonald, R. MacDonald, G. D. McIvor, W. J. McKeand, D. L. McKenna, Ade J. Macmillan, H. D. McPhail, M.A.; W. J. F. Mayne, A. P. Miller, J. Montgomerie, R. Nehru, N. S. Neil, C. T. H. Newton, J. G. Nicholson, M.A.; E. F. W. Nixey, P. G. Palmer, M. D. Rees, D. Ross, Marguerite Ross, D. H. Russell, E. W. Smerdon, H. M. Spoor, L. D. Stephen, W. Stobie, E. A. Strachan, Alice M. Thompson, N. G. Thornley, Helen M'G. Wakefield, W. H. de Water, A. White, R. C. Wuppermann.

UNIVERSITIES OF MANCHESTER, LEEDS, AND SHEFFIELD.

JOINT MATRICULATION BOARD.

THE Joint Matriculation Board of the four universities of Manchester, Liverpool, Leeds, and Sheffield has just issued its report for the year 1908. The board conducts the matriculation examination on behalf of the four universities, and in the past year for the first time the examination has been held under the supervision of education authorities at eight local centres, at which 127 candidates presented themselves. The examination was also taken as a form examination at 28 schools. The total number of candidates at the July examination was 1,695, against 1,294 in the previous July, while in September the number was 519, against 438 in the previous year. As many candidates take the examination a year before they leave school, those who hold the certificates are now allowed to present themselves in a few subjects at the higher standard for supplementary certificates. On behalf of the education committees of Lancashire and Cheshire, the Board has conducted examinations for the award of senior exhibitions and intermediate scholarships offered by these committees. It has also formulated a scheme, which has been accepted by the four universities, for the inspection and examination of schools. The offices of the board have now been removed from Owens College to premises in Dover Street, which is close to the college.

Obituary.

CHARLES COPPINGER, M.D., F.R.C.S.I.,

EMERITUS PROFESSOR IN THE CATHOLIC UNIVERSITY MEDICAL SCHOOL, DUBLIN.

We have to record with very much regret the death of Mr. Charles Coppinger, which occurred in Dublin last week, after a very long period of defective health.

Mr. Coppinger was Surgeon to the Mater Misericordiae Hospital until a few years ago, when he retired from that position. He was also Professor of Physiology in the Catholic University Medical School, and on retiring from his work there he was appointed Emeritus Professor of the Institutes of Medicine. For some years he was a Fellow of the Royal University, and an Examiner in Physiology in that institution. In the Mater Hospital

Mr. Coppinger was for many years a most successful operator, and an energetic and popular clinical teacher. He was one of the few men who have successfully tied the innominate artery. He also did a great deal of very successful joint surgery. In earlier days he was a well-known microscopist. He was a thorough and devoted worker, but for some time he had practically retired owing to continued ill-health. He was naturally of gentle and retiring disposition, but his work was sound and advanced, and he merited greater prominence in his profession than he attained. His pupils and the other friends whom he attached by his kindness and professional knowledge and skill will learn of his death with extreme regret.

Mr. Coppinger, who was unmarried, qualified in 1869. He subsequently became a Fellow of the Royal College of Surgeons and M.D. of the Royal University.

CHARLES KNOTT, M.R.C.P. EDIN.,

PORTSMOUTH.

ON December 29th, 1908, Dr. Charles Knott, of Portsmouth, passed peacefully away. On Christmas Eve he had an apoplectic seizure, and in the intervening days did not recover consciousness. He had been out of health and even ill for some time past, so that his death was not entirely unexpected; nevertheless, its occurrence has been a shock to a locality in which he was as well known as he was highly esteemed, and will be the cause of deep and lasting regret to many in Portsmouth and elsewhere. He received his medical education at Guy's Hospital, becoming M.R.C.S. Eng. and L.R.C.P. Edin. in 1872, being admitted later on to the membership of the latter college. He settled in Portsmouth immediately after receiving his first diploma, and remained steadily at work in the district until late last year, or, in all, for a period of thirty-six years. During the whole of this time he was closely connected with the Poor-law work of Portsmouth, first as a Parish Medical Officer, and for the last twenty years as Medical Superintendent of the workhouse and its infirmary. When he first took over the latter institution it was a workhouse infirmary of the ordinary type of the time, and by no means realized Dr. Knott's conception of what an infirmary should be. He therefore set to work to bring about reforms, and long before he died had been rewarded by a great measure of success, the nursing school which he organized and controlled at the infirmary being of great advantage to the inmates of the infirmary and a credit to Poor-law nursing in general. Poor-law work, however, was by no means his only occupation; he also carried on a large and successful general practice, and held many appointments.

Among other things, he was Chairman of the Portsmouth Centre of the St. John Ambulance Association, a Lecturer to the same body, Medical Referee of Her Majesty's Customs Fund, Medical Officer of Health for Langport and to the Portsea Union House and Schools, and also held until last year a commission in the 3rd Volunteer Battalion of the Hampshire Regiment. He joined this force in 1882, raised and trained an excellent bearer company, received the Volunteer Decoration, and eventually became Surgeon-Colonel, retiring on the transformation of the battalion into the 6th Hampshire Territorials. His connexion with the St. John Ambulance Association was also long, and his services to it so marked that a few years ago he was honoured by being appointed a Knight of Grace.

For several years he held a seat on the Portsmouth School Board, and throughout his career exhibited a constant interest in children. His sympathy with young people may, indeed, be regarded as one of his strongest characteristics, and it was, perhaps, as much for their sake as in honour of Charles Dickens—whose birthplace was Portsmouth—that he set himself to work on a task the achievement of which he regarded with great satisfaction—namely, the raising of a fund for the maintenance of the "Tiny Tim" bed at his old hospital, Guy's.

Popular as was Dr. Charles Knott with the general public, he was equally esteemed by his professional brethren, and some eight years ago, when the British Medical Association held its annual meeting in Portsmouth, he was President of the Southern Branch. He was, indeed, one of the original members of this Branch, and maintained his interest in the affairs of the Association right up to the end.

Dr. G. P. M. WOODWARD, who died recently at Sydney, was the son of the late Mr. Wm. Woodward, of Clough Prior Castle, co. Tipperary. He obtained the diploma of L.R.C.S.I. in 1850, and that of L.R.C.P.I. in the following year, taking the Fellowship of the Royal College of Surgeons in Ireland in 1879. He joined the Ordnance Department of the army in 1851, and in December, 1853, was promoted surgeon from the Royal Artillery, with which regiment he had served in the Crimea, including the siege and fall of Sebastopol, receiving a medal with clasp, and the Turkish medal. Dr. Woodward again saw active service, this time with the Royal Horse Artillery, during the Indian Mutiny in pursuit of Tantia Topce in Central India in 1858-9, for which he received a medal; he also held the medal for service throughout the Abyssinian campaign of 1867-8 as a staff surgeon in charge of the hospital ship *Mauritius*. He retired with the honorary rank of Deputy Surgeon-General in 1877. Dr. Woodward went to Australia, and about 1882 joined the medical staff of the railways, with which he retained connexion until his death. The railway department was well represented at the funeral on October 6th.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. M. N. Popoff, Professor of Neurology and Psychiatry in the University of Tomsk; Dr. D. J. Kurajeff, Professor of Medical Chemistry in the University of Charkoff; Dr. Epiphany Marques, Emeritus Professor in the Medical Faculty of the University of Coimbra, Portugal, administrator of the hospitals of the university, and author of some works on medical subjects; Dr. E. Delbet, Member of the Chamber of Deputies for the Seine-et-Marne; and Dr. René Blache, Member of the Académie de Médecine, General Treasurer of the French Medical Association.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

SANITATION IN THE COUNTY OF DURHAM.

ALTHOUGH county councils possess very little active power over defaulting sanitary authorities, they are armed with means for putting into action the powers of the Local Government Board. Complaint may be made by a county council under Sec. 299 of the Public Health Act, 1875, if in the opinion of the council an authority is not providing its district with sufficient sewers, is not maintaining those which do exist, is not providing a sufficient water supply, or in other ways is not enforcing the provisions of the Act of 1875. Very few county councils have taken advantage of this section, and some of those who have seem to have met in some instances with only scanty support from the central authority.

The county council of Durham was among the first to use the section for the purpose of hastening public health reforms within the county, and, in spite of rebuffs, is continuing this course of action. The recently issued report to the Local Government Board of Dr. R. J. Reece gives an account of the circumstances which induced the county council to make complaint in July, 1906, of the default of the Hebburn Urban District Council. During the two years which had elapsed between the date of the complaint and the inspection of the district by Dr. Reece, a certain amount of activity had been displayed by the district council, and he had principally to inquire into the defaults of the council in not putting into force its powers with respect to insanitary houses and out-offices. In 1901 there were 2,784 houses in Hebburn, and of these nearly 700 are owned by the Hebburn Colliery Company. It is with these last, of which about 150 are said to be in an insanitary condition, that the greatest difficulties have arisen. The cost of working the colliery is very great, on account of the large amount of pumping necessary, and the thicker seams of coal are getting exhausted. No dividends have been paid to the ordinary shareholders, and at any time the directors may consider the desirability of closing the colliery. The company's houses are occupied by the colliers rent free, and if they are turned out of the worst houses the company would be required to pay a rent allowance, amounting in the aggregate to £1,000 per annum, in accordance with the custom in the Durham coalfields. The question of improved dwellings is thus complicated in a manner not to be found except in the coalfields of Durham and Northumberland; but there can be no doubt that the inspection which has been made by Dr. Reece and the report which has resulted from that inspection will go some way towards creating improved conditions, for it is written in a most reasonable and judicious spirit, which cannot fail to be appreciated by those who are most intimately concerned in the welfare of the district.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL CHANGE OF ADDRESS.

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL have been removed to 429, Strand.

COMMUNICATIONS respecting Editorial matters should be addressed to THE EDITOR, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Asiologia, London*. The telegraphic address of the MANAGER of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONS (National).—

EDITOR,

2631, Gerrard.

GENERAL SECRETARY AND MANAGER,

2630, Gerrard.

MEDICAL SECRETARY, 2634, Gerrard.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Manager, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE REFERRED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "Enquirer," and so on. By attention to this request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

W. B. would be glad of references to papers giving most up-to-date information as to the treatment of phthisis by tuberculin, by cinchinate of sodium, by serums, and by graduated exercise, as at the sanatorium in connexion with Brompton.

DIRTY HEADS AND FOOD FACTORIES.

TRANSFORTHANA writes: As a medical inspector of public schools I have, in common with others, had an eye- opener regarding the prevalence of lice and nits in girls' heads. I am a M.O.H. and an inspector of factories. In one school, where food products are made, many "young persons" are employed. Is it my duty to examine these girls' heads; and if lice and nits are found, ought I to reject the candidates? The factor does not consider himself "responsible for the health of the girls in his employ," but expects the M.O.H. to do what is "right and necessary under the Act."

TYPHOID FEVER AND INTESTINAL INFECTIONS.

DR. C. L. FRASER, F.R.C.P., F.R.C.S. Edin. (Berwick-on-Tweed), writes: During the past year it has been my fortune to meet with several cases which presented all or nearly all of the characteristic symptoms of enteric fever. The clinical picture in each instance was as nearly perfect as it is possible to portray the disease, and speaking clinically no doctor of average M.O.H. and an inspector of factories. In one school, where food products are made, many "young persons" are employed. Is it my duty to examine these girls' heads; and if lice and nits are found, ought I to reject the candidates? The factor does not consider himself "responsible for the health of the girls in his employ," but expects the M.O.H. to do what is "right and necessary under the Act."

FORENSIC ASPECTS OF MENSTRUATION AND PREGNANCY.

DR. HORACE G. COLE (Liverpool) writes: Apropos of your article in the JOURNAL of December 12th, 1908, some of your readers, especially those of a psychologically obstetrical turn of mind, might be interested in a case which I am attending. The patient is a healthy woman, aged 33, who has been married nearly a year. Before marriage the catamenia were regular, painless, usually lasted a week, and were unaccompanied by any special psychoses. Before marriage took place it was noticed that the lady became irritable at times. This irritability did not incapacitate her for work, and, indeed, would not be noticed except by those with whom she was very intimate. Ten days after marriage the patient became quite choleric, the fit of angry temper being occasioned by some trifling matter. A week later she menstruated. The same thing—that is, irritability of temper—happened the next three times in each case a week previous to menstruation. Three weeks after the last period she spent the greater part of the night in a nearly hysterical condition. She absolutely refused to give any reason for her laceration. She did not menstruate that month, nor has she done so since. She is expecting her confinement shortly. With the exception of psychical disturbances, pregnancy has run an uninterrupted and typical course; but in regular periodicity these cerebral explosions have taken place. If the patient recollects before-hand, she is able to conquer her animosity to her husband, but, instead, becomes intensely miserable and cries for days at times. At the last attack, during her husband's absence, she had a great desire to open a vein with a pair of scissors—she could think of no other way of getting rid of herself—but decided it might hurt! This has been the only suggestion of suicide in the case. The above data were given to me by the husband; but he seems a very observant man, and there is no reason to doubt his veracity. Both he and his wife seem greatly attached to one another, and he is anxious about the future. I should be glad if readers would offer some suggestions as to treatment.

INCOME TAX.

TAXPAYER writes, with reference to an answer given to him in the BRITISH MEDICAL JOURNAL for December 12th, 1908: If profits of practice are, say, £410, there is an abatement on £150 of this. If in addition to this there is private income of, say, self £200, and wife £50 all of which £250 has already had tax deducted before dividends are received, the total income is assessed at £410+£200+£50=£660, and abatement allowed only on £70—(1) Is this assessment correct? (2) Or can abatement on £150 be properly claimed? or (3) return of tax on the £250 private income be properly claimed? and (4) in case of either (2) or (3) how long after assessment can claim be made by the taxpayer, and what arrears of charges can be recovered?

* (1) The correct assessment is £410, less £70 abatement—that is, £340. The answers to the remaining questions are: (2) No. (3) No. (4) No reply is necessary.

HIRDO writes: Can I appeal against my assessment on the ground that my income for the three previous years has not been taken into account? I am now assistant at £200 a year, and my income up to April, 1909, was returned as that, but previously my incomes as house-surgeon, locum, etc., were £60, £100, £75, an average of £78 1/3 per annum. . . Is it worth while appealing, apart from the fact that only 30s. is in question?

* The time for objecting to the assessment has gone by, and, unless the Commissioners are willing to hear an appeal, our correspondent is out of court. If the Commissioners permit an appeal to be made, the question raised is one for them to determine. It is probable that they would allow the average to be taken as claimed by our correspondent. If, however, they take the opposite view, the case does not appear to be of sufficient importance to make it worth while to contest the decision of the Commissioners in the High Court.

ANSWERS.

R. S. H.—A lecture by Dr. G. E. Herman in which the treatment of retroversion and retroflexion of the gravid uterus was discussed appeared in our issue of April 16th, 1904.

FLEET SURGEON.—In normal vaccinia there is no material present that clinically would be called pus. The contents of the vesicle may become puriform by the accidental access of extraneous organisms, but the observance of the simple precautions now universally enjoined easily obviates this. An account of the histological appearances in the vaccine vesicle and the chemistry and morphology of vaccine lymph is given in *Vaccination: Its Natural History and Pathology*, by Dr. S. Monckton Copeman (London: Macmillan and Co., 1899, 6s.).

LECTURES TO PROBATIONER NURSES.

INFIRMARIUS.—The best way of preparing a syllabus for a course of lectures to probationer nurses would probably be to get a good elementary textbook on physiology and another on nursing and look through them, as there does not seem to be any outline of such a course published. The following works might be consulted: *Mechan's First Stage of Human*

Physiology (London: W. B. Clive, University Tutorial Press); *Lewis's Nursing: Its Theory and Practice*, eleventh edition (London: The Scientific Press, 2s. 10d. net.); Foster and Shore's *Physiology for Beginners* (London: Macmillan and Co., 1894, 2s. 6d.); and Miss Lücke's *General Nursing*, sixth edition (London: Kegan Paul, Trench, Trubner, and Co., 1905, 5s.).

NICOTINE AND TORRACO.

A. N.—The figures given in reply to "J. F. M." (BRITISH MEDICAL JOURNAL, December 19th, 1908, p. 1548) for the percentages of nicotine in tobacco (1.5 to 3 per cent.), were collected from results published by different workers at various times. The figure 1.5 was taken from a series of analyses of different tobaccos made in Italy some years ago; the actual figure given was 1.62 per cent. on the dried leaf, and as the leaf may contain anything up to 35 per cent. of moisture, this would give 1.5 or less per cent. on the air-dry tobacco; the only information given about this sample is that it was Havana tobacco. This is in agreement with such results (few in number as have been obtained by our analyst, who has found much less nicotine in cigars than in pipe tobacco). The subject, however, would require further investigation before any general statement could be made.

TREATMENT OF FOLLICULAR STOMATITIS.

DR. R. M. FRASER (Belfast) writes: The condition to which "W. M." has drawn attention, though not excessively rare, is not mentioned in any literature I have consulted. I should feel obliged if "W. M." would supplement his description by stating whether a vulcanite dental plate is worn, and, if so, is it kept in night and day? and also, in reference to the vulvar condition, whether a pessary is worn. In a patient of my own I made, without success, an attempt to make a culture from a vesicle. Perhaps some dental practitioner could throw light on the matter as to whether it is due to some susceptibility to rubber. Drugs appear useless.

LETTERS, NOTES, ETC.

A WARNING.

DR. A. G. BATEMAN (General Medical Officer, Medical Defence Union, 4, Trafalgar Square, W.C.) writes: May I ask, through your columns, medical practitioners who may be applied to for pecuniary or other assistance by a person calling himself "Dr. J. Backus Taylor, M.R.C.S., L.R.C.P.," not to grant any such aid without first communicating with me? Medical agents should also guard themselves in a similar manner before placing the name of this person upon their lists for employment as assistant or locum-tenent and sending him to clients. There is a Dr. Backus Taylor upon the *Medical Register*; but from circumstances which have come to my knowledge it would be as well not to assume that the individual of whom I write is the qualified practitioner of that name in the *Register*. I shall be glad to afford any information to any one applying to me either personally or by letter.

GLASSWORKERS' CATARACT.

In the notice of the *Second Report of the Departmental Committee on Compensation for Industrial Diseases* published last week, p. 28, in line 25 from top, first column, Dr. Legge was unfortunately misrepresented; it should have been stated that he reported "that all classes of glass furnace workers appeared to suffer," not all glassworkers.

LACTIC ACID BACILLI.

DR. GEORGE HENSHELL (London, W.) writes: Dr. Bushnell's advocacy of the use of cultures of lactic acid bacilli in liquid form whilst admirable in theory is, I am afraid, impossible in actual practice, mainly from the impossibility of securing delivery of such cultures commercially at the patient's house. Whilst agreeing with his contention, I have for some time abandoned the use of them in favour of dried cultures, with which I have obtained the best results. As regards the contamination of the latter, whilst considerable in the case of tablets made from inspissated milk, it may be neglected in those manufactured simply by the addition of an inert powder to the dried bacilli. In these the contamination from the air is not greater than we find in most ordinary articles of diet. I should like to ask Dr. Bushnell whether the Thermos flask will stand sterilization by boiling.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

					£	s.	d.
Eight lines and under	0	4	0
Each additional line	0	0	6
A whole column	2	13	4
A page	8	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

A.B.—It is against the rules of the Post Office to receive letters at *Teste Restante* addressed either in initials or numbers.

An Address

ENTITLED

ALPINE OR HOME CLIMATES FOR EARLY TUBERCULOSIS?

DELIVERED AT THE MEDICAL GRADUATES' COLLEGE
AND POLYCLINIC.

By WILLIAM EWART, M.D.CANTAB., F.R.C.P.

CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL; SENIOR PHYSICIAN
TO THE BELGRAVE HOSPITAL FOR CHILDREN; JOINT HONORARY
SECRETARY TO THE QUEEN ALEXANDRA SANATORIUM, DAVOS.

This question has a practical bearing which is soon to become obvious in a novel aspect—that of the sanatorium patient. The best means for arresting tuberculosis in the individual and the community have always had the attention of the large body of practitioners to which you belong. But it will happen to many of them in the near future to be responsibly concerned with the task of selecting and certifying suitable cases for the great opportunities which will soon be offered by the Queen Alexandra Sanatorium at Davos.

THE QUEEN ALEXANDRA SANATORIUM, DAVOS.

The Sanatorium, which was mentioned by His Majesty the King at the opening of the King Edward VII Sanatorium on June 13th, 1905, as having Her Majesty the Queen for its Patron, and the privilege to be permitted to be called by her name, is now within measurable distance of entering upon its career of usefulness as our only National Sanatorium in the most perfect of all known climatic resorts for pulmonary consumption. It is not yet completed, though its stately mass already overlooks Davos from a commanding site. The delay is still due to the lack of that powerful philanthropy which would not long be withheld from it were we as a body to lend our united forces to a support of its claims.

This is not, however, an appeal for funds, although there is no other profession with wider opportunities to guide private munificence into the most deserving channels. Our study to-day is not that of subsidies, but how we shall turn to the best account the provision, second to none as regards comfort and efficiency, which is being made for our patients at the Queen's great Alpine Sanatorium.

Concerning the national importance of that object, and in extenuation of the reproach of our lateness in carrying it out as compared with some other nationalities, it is gratifying to think that its first tentative embodiment in Davos arose within the British community with the devoted personal labours of the late Mrs. Lord in the service of our poor consumptives, whose welfare is now under the efficient care of the Local Board of Management. The national aim pursued for years by the "Davos Invalids' Home" to provide a sanatorium worthy of the two great English-speaking nationalities, on an excellent site, purchased mainly through the exertions and the generosity of my lamented friend and co-secretary, the late Mr. Arthur Herbert, had received Royal recognition before the end of the century, and upon her accession in 1901 Her Gracious Majesty was pleased to confirm the patronage which she had granted to the "Home" as Princess of Wales.

But the great Queen Alexandra Sanatorium, which now crowns the southern extremity of Davos at an altitude higher than that occupied by any other national sanatorium in Europe, would not have become an accomplished fact but for the quite unparalleled energy and success of our President, the Lord Balfour of Burleigh, in preaching the good cause, not only in Davos, where the British colony has evinced much public spirit, but far and wide throughout the United Kingdom. The indefatigable services of my co-secretary, Mr. D. A. F. Vesey, and of Mr. H. C. Wrinch, our local secretary at Davos, and the work of the Local Board of Management, under the chairmanship of His Majesty's British Consul, Dr. W. Huggard, have all been essential also to the achievement.

THE SELECTION OF CLIMATE AND OF CASES.

Owing to those early beginnings, experience has been accumulating, both from our own work and from that of other institutions in Davos, which will prove of advantage. Without undue presumption we may therefore hope that the future working of the Queen's Sanatorium shall be unsurpassed in the results of treatment. One condition is, however, absolutely indispensable, and that is that we shall have throughout the country your constant co-operation in sending us the most suitable cases. That consideration now prompts me to place before you to-day as

briefly and as clearly as I can the leading notions which may guide your action. I shall, in the first place, endeavour to satisfy you as to the practical soundness of *two propositions* and as to the detrimental influence of *three popular fallacies* in connexion with the full exploitation of the altitude for the cure of tuberculosis.

THE POLICY OF COMBINATION AND SOME PREVAILING MISCONCEPTIONS.

The Policy of Combination.—The two propositions I wish to establish make for one practical conclusion—namely, that our true policy is one of a *systematic combination for individual cases of the Alpine and of the Home Sanatorium treatment*.

Proposition I. The best possible value will be got from the Home sanatorium treatment for early tuberculosis when the patients shall have had the advantage of a preliminary course at the Alps.

Proposition II. The best results are obtained at Davos when patients resort to it at their earliest stage, before any time has been spent over any other form of treatment, whether at their homes or at any of our Home sanatoriums.

The Three Prevailing Misconceptions.—*First Fallacy:*—"All climates are sufficiently good. Everywhere it is the open-air that cures, and this can be had at home." To those of you who have travelled for recuperation after hard work the suitable reply does not need to be suggested. The extent of your gain in health has been conspicuously varied in different localities, according to the kind of open air you have enjoyed.

Second Fallacy:—"The winter is the time for Davos. Let us wait till December, and spend this summer and autumn at home." Our brief answer to this too often fatal misconception is the object lesson afforded by the Davos list of visitors. The most precarious of patients, those *chronic miracles* showing arrest and survival in the advanced stages, are those who find it good to remain in permanent residence at Davos through summer and winter alike. The worst sample of Davos climate, if good for them, should be good enough for our early cases. There need be, then, no closed time for the blessings of the Queen's Sanatorium.

Third Fallacy:—"Try England first and our Home Sanatoriums. It will be time later to fall back upon Davos in second resort." Our safeguard against this fallacy is not merely historical evidence. In the course of annual winter visits to Davos and the Alps during the last twenty-five years I have known patients who had been attracted to the Alps from the Rocky Mountains, and others from high valleys south of the Himalayas. We must bear in mind that the same degrees of altitude are available in many parts of the world, but the climates of these identical altitudes differ in all of them. The same holds good within quite small districts. One of the earliest climatic lessons which I learned was the considerable differences in the individual merits of climates such as those of St. Moritz, the Maloja, Davos-Platz, Wiesen, Arosa, and others, all of them within the same Alpine group. Of course, much greater differences must occur between the mountain climates of different latitudes. In face of these practical differences between valley and valley, need we labour the point that there is an objective importance, and not mere fancy, in the larger question as to the treatment of a patient in the altitude or in the plain.

THE COMPARATIVE VALUE OF HOME AND ALPINE SANATORIUM TREATMENT.

The two great national institutions referred to may be said fairly to represent two rather diverging lines, between which a choice has to be made in the class of cases we have under consideration: the Midhurst Sanatorium, as the type of the many excellent Home sanatoriums—still too few for our needs—the efficient work of which is indispensable as our chief weapon in the fight against tuberculosis, and as the type of the best that circumstances can at the present time offer in this country for the greater number; the Davos Sanatorium, a special effort to carry out for a smaller number the special advantages *not* to be found in this country, and which it is unhappily impossible to procure for the masses—as the type of the best climatic cure which the world can provide.

In our recent climatic therapeutics there has been a tendency to ignore, and another tendency to exaggerate, the therapeutic importance of differences between climates. The practical effect of both is to deprive our patients of some valuable climatic opportunities. Usually the home climates have been favoured; but the opposite has also been known to occur. The welfare of individuals and of the community may probably be better served by the view I have submitted that there is in most cases an excellent alternative in their happy combination. I had previously expressed an opinion that a majority of cases of pulmonary tuberculosis are at an early stage suitable for the Alps. I should like to add the further opinion that a majority of them are curable at home if only treated early enough. These two statements taken together amount to saying that for most of our cases there is a cure both at home and abroad.

The point which arises is whether patients would be any the less curable at our Home Sanatoriums if they had previously taken an early and short instalment of the Alpine cure. *Esperanto credo*, the best answer is to be got only from those who have tried that plan. A further point is whether, just as there are cases which are not suited for the Alps, there may not be some, too, not perfectly suited by our home climates, and which the Alps might suit in a special degree. If we admit the existence of these two minorities outside the majority for which our home sanatoriums are available and for which Alpine treatment would also be suitable, the importance of an "early" selection of the best climate is apparent.

The Alternative of the Alps as an Alternative of Choice or as an Alternative of Necessity.—For the masses, under existing conditions, the alternative does not arise. We are dealing only with those for whom travel and residence abroad are practicable. For many of the latter the alternative of the Alps is, like the better of two good things, a luxury. They can be got well without it in "the long run." And if their choice should have been made for the "longer run" there is safety in the end; or, at any rate, there need be no disaster. But when it happens that a patient has not made sufficient progress in the Home sanatorium, in spite of a fairly long trial, the alternative of the Alps is no longer to be regarded as one of choice but of necessity. Would that he had originally chosen rather than eventually suffered that alternative. Although at the latest date he may yet succeed in securing his life, this cannot now be done without a considerable expenditure of time and of money. These are the uncertain cases which the climatic adviser should have constantly in mind in his chest examinations of early applicants. These are also the best cases to illustrate the other aspect of the same question—the wisdom not of an exclusive selection of one or the other form of sanatorium treatment, but rather of their *systematic combination*; for in that combination, if only it could be adopted in time and in the proper order, lies not only the safety of many a sufferer, but the best saving of expenditure and of earning capacity.

The Alpine Cure Largely Climatic, the Home Cure mainly by Open Air.—The history of the Alpine treatment is instructive. Dr. Spengler began his climatic cure in Davos in 1853, because that valley had been known as far back as the Middle Ages to be free from endemic consumption. In those days, however, perpetual open air, which had already been preached by Bodington in this country, was still farther than it is even now from prevailing among the local population. During the long winter months house hygiene, particularly as regards ventilation, was worse than it is in our great cities. Nevertheless, though the women, for whom there was little outdoor occupation, suffered from anaemia, yet in spite of the long period spent in bad air, they did not develop consumption. This brings very clearly into light the existence of three distinct aëro-therapeutic values in the air-treatment of consumption: (1) Facilities for a perpetual open-air life; (2) freedom from germs; (3) specific climatic quality. In the past the secular immunity of the Alpine altitude from tuberculosis was not due to the first of these values, but existed in spite of its utter neglect. There must have been a singular redeeming virtue in the other two.

In these islands a strictly perpetual open-air life is a preservative and also a cure. But, failing that open-air life, the climate does not possess the qualities which will prevent or check the spread of tuberculosis. In short,

whilst the fullness of the open-air treatment is indispensable in the Home cure, the Alpine cure is not entirely defeated by its incomplete application. Or to state the same thing rather differently: When we take with us the open-air cure to the Alps we are adding excellence to that which is essentially, on its own merits, very good.

The Nature of the Alpine Climatic Advantage.

"Increased vitality" expresses better than any other term the benefit which is conferred. It is felt even by confirmed consumptives and brightens, if it cannot always lengthen, their remaining days. The long survival at Davos of some much advanced cases is a striking proof in point. But we had better look for a demonstration of this remarkable vitalizing power at the other end of the scale—in the man or child who might become a consumptive but is now only depressed by previous illness, overwork, or any lowering circumstances. Why do we send to the Alps the jaded city clerk, the neurasthenic overworked curate, the anaemic exhausted nurse or school mistress? Because there is no change of air which will effect in them with greater certainty a greater change in an equally short time.

The mechanism of these resurrections in vital energy is too well known to you to need more than bare enumeration. Rarefaction of air, dryness of air, and stillness of air, actinic equivalent, and light and warmth equivalent of the sun's rays, physical and mental inspiration from the surroundings, all these factors combine with the influence of the elevation itself and with others perhaps still unknown, such as radio-activity, etc., to render this the strongest of all stimulations: (1) For the nervous system; (2) for the alimentary and metabolic functions; (3) for the richness of the blood; (4) for the nutrition and working power of the heart and of the circulation; (5) for the expansion of the chest, and (6) for the strengthening of the lungs and of respiration.

The immediate rebound is merely the setting free of a hidden store of energy. Where that store is nearly exhausted, this great rapidity of rebound is no longer possible. In the end, too, pilgrims to the Alps will carry away from the mountain just as much proportionate increase in their vitality as they brought to it of vital reserve. Passing to those suffering from tuberculosis, it is clear that a *phenomenally rapid result* of the kind described is attainable only in a patient who has not yet allowed much of his available store of vitality to be wasted by delay under less active measures. His one great opportunity for a rapid cure by the Alpine treatment comes never again; it exists only at the earliest beginning of his degeneracy.

The Mechanism of the Cure of Tuberculosis.—This estimate of the patient's best chances is supported by the latest views as to Nature's method of cure. This is not through the direct operation of our remedies—food, tonic medicines, bracing air, sunlight, rest, graduated exercise, etc.—upon the bacilli or their venom, but through the much more direct operation upon them of our own scavenger and other cells. The *hygiene of disease*, if I may venture to use that expression, consists in raising to the highest pitch the efficiency of our physiological scavenging department and of the protective powers of our juices, at the approach and under the stress of infection. If the energy of our phagocytes should fail to be raised in time to the point of clearing the field whilst the invaders are still few, every passing day will lower it whilst adding to the strength of the invading host. Recovery can no longer be rapid, and it soon becomes precarious.

The Sliding Scale of Profit Derivable from the Alpine Treatment.—If a man were to be offered an assured and profitable investment, he would not continue spending his capital till little of it remained to invest, but would invest at once, and endeavour henceforth to live upon the interest. It is equally true in the matter of health values, that the profit varies with the capital invested.

1. Take the strong man or child whose health is only depressed. He can make the best use of the mountain, and obtain all the good it can give almost without any delay.

2. A less robust subject already threatened with tubercle, though not yet infected, will be able to use the mountain less freely. His profit will be more gradual, yet great in

the end, as it will amount to a practical guarantee of future health, and of freedom from infection.

3. But for the tubercle-infected patient there will be much less activity and much less gain. Even at an early onset of the trouble, it will take *weeks instead of days for the mountain* to make him well.

4. Comes the stage of early bronchial and pulmonary lesion. Our patient is now an *invalid*. Happy if at that time his lot should be cast in the heights where lungs are less slow to heal. But there is at first no active use in the mountain for him; for a while he must simply lie and breathe its atmosphere. He has missed the quick cure. Instead of only weeks, the mountain must now claim *months of his life* to make him safe for the remainder; and with rare exceptions it will never succeed in making a good mountaineer of him.

5. Least of all is this an ambition to be indulged in by those far advanced and badly damaged. Henceforth *mountain-dwellers for life*, or for long periods of time, they can only slowly pace the valley, content to secure from the mountain just their breath and their being.

THE UNSUITABLE AND THE SUITABLE CASES FOR ALPINE TREATMENT OR FOR ADMISSION INTO THE SANATORIUM.

Particulars will in due course be published of the decisions of the Council as to the conditions for the admission, residence, and discharge of patients. As an unlimited stay would not be practicable, and as, in fairness to other candidates on the waiting list, a comparatively short period, possibly renewable, would have to be enforced as is the custom elsewhere, the question of admissibility will have to be most carefully considered by the honorary examining physicians. Unsuitability for admission need not, therefore, imply unsuitability for altitude treatment *per se*. For instance, great advantage might be ultimately derived in Davos by a patient whose condition at the time of application might have been judged to be too precarious to guarantee adequate benefit even from a fairly prolonged stay in the Sanatorium.

The general question as to *suitability for Davos* is quite separate. It is a much more difficult one than that which is before us to day, as it includes a consideration of many confirmed cases, which the sanatorium has to decline, and which we need therefore only mention very briefly.

The Unsuitable Cases for Altitude Treatment.

As a general statement, it may be said that a *majority of all cases* of pulmonary tubercle are suitable for altitude treatment. The minority is that of the unsuitables, and is made up as follows:

1. The Advanced Cases:

- (a) In their terminal stages; or
- (b) With severe visceral complications—cardiac, vascular, renal, gastro-intestinal, hepatic, nervous, alcoholic, etc.; or
- (c) With specially adverse respiratory affections, such as catarrhal bronchitis, asthma, bronchiectasis, emphysema, late laryngeal tuberculosis, and others.

2. The Relatively Early Cases:

- (a) With much catarrhal pneumonia; or
- (b) With active tuberculization, as evidenced by persistent pyrexia, wasting, rapidity of pulse and of respiration; or
- (c) With considerable tendency to hæmoptysis; or
- (d) With any of the pulmonary or of the visceral complications mentioned above; but the cases of quite early laryngeal tuberculosis have to be considered on their individual merits.

The Suitable Cases.

The suitable cases (for the altitude, but not necessarily for the sanatorium) form the majority. They may be taken in the following groups:

GROUP I. *The Chronic Cases* differ much as to their amenability to the curative influence. Although many of them do very well in *permanent residence* in the altitude, they are not, strictly speaking, curable, even at Davos. Much less are they "short-treatment cases." They are not, therefore, suitable in that sense for the Sanatorium.

GROUP II. *The Stages of Confirmed and Active Tuberculosis*.—Many, although not all, cases at these stages are

better suited by the altitude climate than by any other. But as, even in the altitude, they are all slow to heal, their alpine cure has to be reckoned in *months or even in years* during which to send them home would amount to interrupting, and often to ending, progress towards recovery. A few patients of this sort, if they had to be "seen through" their trouble, would monopolize beds to the exclusion of large numbers of "short-treatment cases." Although they may be thoroughly suitable for Davos, the Sanatorium could not undertake the responsibility of such prolonged cures without serious detriment to the interests of the community.

GROUP III. *Early Cases of Mild Type, with Localized Physical Signs of Early Lesion, and with good Antecedents*.—These are eminently suitable for the altitude, and in a large proportion are quickly curable there. They are, of course, admirably suited for a stay in the Sanatorium, followed by a course of treatment at a Home Sanatorium. This is at present and is likely to remain a large group, as many who belong to it are originally of good stamina, and are apt to defer submitting to a medical examination until early physical signs have developed. If sent immediately to the Queen Alexandra Sanatorium, these patients would contribute to a large turn-over of successful "short treatment cases."

GROUP IV. *Early and Mild Latent Cases, without Physical Signs, but Identified as "Tubercle."*—These are the ideal cases for the altitude and for the Sanatorium, because their tuberculosis can be arrested and their chest considerably strengthened by a few weeks' stay in the Alps, with a practical certainty such as is probably not to be equalled in any other climate. After that stay they should immediately proceed to a Home sanatorium to confirm their gain.

GROUP V. *Early Latent Tuberculosis Diagnosed but not Identified*.—This, too, is an ideal field for the best work of the altitude and of the Sanatorium. All the members of this group, whether rightly or wrongly suspected of pulmonary tuberculosis, are sure to derive in a few weeks' stay at the Sanatorium, followed by Home sanatorium treatment, an amount of general and cardio-pulmonary invigoration which will permanently raise them above the danger-line of that "tubercle-catching level" at which they have been living.

It is inevitable that in that number some should be included in whom tuberculosis is really not present, but is only simulated by that *misère physiologique* which is its usual forerunner. Call them "pretubercular" if you will; the name matters little so long as they are not deprived on sentimental grounds of the immense and unmitigated benefit provided by the Sanatorium.

GROUP VI. *The Preventorium Cases*.—This is the group of the most suitable of all cases for the altitude, as they are capable of yielding with the least delay the most brilliant results. But, as tubercle has not been diagnosed in them as present, but only as threatening, they may not claim admission into the Sanatorium. A large, and the most important, proportion of this group is composed of delicate children. Special provision for them in the Alps combined with a Home of Rest for Nurses is one of the most beneficent future developments of the work of the Queen Alexandra Sanatorium to which any large benefit could possibly be applied.

CONCLUSIONS AS TO THE BEST PRACTICAL ADVICE FOR "SANATORIUM CASES."

1. It would be worth everything to a merely threatened subject to be sent to the Alps before tuberculosis had actually set in. In the future, perhaps, this may be possible in connexion with some *Alpine Preventorium*, such as was suggested in my article in the *Practitioner* for July, 1908.

2. For the Sanatorium-cure, as it now exists, the patient's best chance occurs *immediately* when the existence of tuberculosis is diagnosed or strongly suspected. At this earliest stage proper treatment will do more good than at any other stage, and more good will be secured at an Alpine than at any other sanatorium.

3. As in many of these earliest cases the improvement obtainable in the altitude is very rapid, four to six weeks' stay at Davos may place the further progress of the case beyond any risk of relapse, provided the open-air treatment be continued for a further period at any suitable

Home Sanatorium to consolidate the cure. Arrangements should therefore be made accordingly in good time.

The "short and early" *Alpine* cure is the best of all courses for safety and also for real economy. Too often patients are sent to the altitude as a last resource. If, as this implies, there is a curative power in it greater than that of home climates and to which an ultimate appeal has to be made, the patient would have been better off for its earlier help. In fatal cases life itself might perhaps have been saved. In the others there might have been much saving of time and of earning power to outweigh the additional expense of travel. For, although both forms of sanatorium treatment yield their best results at the earliest stage, the advantage arising from earliness, particularly as regards rapid results, is immeasurably greater in the Alps than in our own climate. Safety and economy strongly urge that the *Alpine Sanatorium* should be visited not second, but first.

4. The rationale for this order of march rests upon:

(a) The greater "altitude invigoration" which can be derived by constitutions as yet less debilitated by disease, and upon the greater "altitude expansion" of lungs as yet less extensively damaged; and also

(b) Upon the greatly enhanced subsequent efficiency of the *Home sanatorium* treatment when the early cases have just had the benefit of that initial invigoration and of that thoracic expansion which no *Home climate* can confer.

5. The *Selection of Cases* is simplified by the fact that, at that earliest stage, practically speaking all ordinary apyrexial cases are suitable for a temporary stay in the altitude.

6. The *Selection of Seasons* is simplified by the fact that for these earliest cases all seasons are suitable for treatment under sanatorium rule. As a fact, the individual merits of the several seasons are a minor consideration as compared with the inherent virtues of the "mountain breathing-cure," and these are always equally at our service at all times of the year.

7. As no other treatment is superior to this, no points can possibly be lost through its immediate adoption. But many points might be quickly lost through its delay. For safety, our first climatic prescription should be in all "possible" cases, "Sanatorium treatment in the Alps at once, and *Home Sanatorium* treatment to follow."

8. For those threatened only—and particularly for *Children*—this is the treatment *par excellence*; and for them *Alpine preventoria* must eventually be provided. The risk of bacillary infection, which has sometimes been alleged as a deterrent, is probably smaller at *Davos* than anywhere else; and as a merely sentimental objection it should not be allowed to stand in the way of an untold boon.

9. The later cases, including those which have not been cured by prolonged treatment at our *Home Sanatoriums*, are not to-day under our consideration. For them the best opportunity has clearly been missed. Nevertheless they may still find in the altitude a measure of improvement greater than they could obtain elsewhere, provided they can invest considerable time in their treatment. These are not the cases in which admission to the *Queen Alexandra Sanatorium* could lead to the best and to the most rapid results, nor to the greatest advantage for the greatest number. They are not therefore specially the cases which you will be invited to recommend when the *Sanatorium*, at no distant period as it is hoped, shall at last open its gates.

The German Society of Tropical Hygiene will hold its second meeting in Berlin at Eastertide this year.

According to the *Medizinalkalender für Oesterreich*, the number of medical practitioners in Austria, including *Bosnia and Herzegovina*, at the end of 1908 was 12,278, as against 12,041 in the previous year. Of these, 2,946 reside in Vienna, 269 at *Graz*, 112 at *Innsbruck*, 499 at *Prague*, and 334 at *Lemberg*.

The eighth International Congress of Hydrology, Climatology, Geology, and Physiotherapy will be held this year at *Algiers*, April 4th to 10th, under the patronage of M. Jonart, Governor-General of *Algeria*. There will be an exhibition in connexion with the Congress, and a number of interesting excursions have been arranged. Communications relative to the Congress should be addressed to the General Secretary, Dr. L. Reynaud, 7, Place de la République, *Algiers*.

THE SELECTION OF SANATORIUM CASES FOR TREATMENT WITH TUBERCULIN.

By H. HYSLOP THOMSON, M.D.,

MEIKEN, CHILTERNENTMENT, LIVERPOOL SANATORIUM,
DELSWATER FOREST.

THE scientific and comprehensive basis upon which the sanatorium treatment of tuberculosis has now been placed is chiefly due to the exhaustive work of Wright on the problem of the infections and their treatment by opsonotherapy. The recognition of autoinoculation as a specific factor in the treatment of disease took origin in the observations of Freeman. The possibilities of autoinoculation in the treatment of pulmonary tuberculosis were first recognized by Meakin and Wheeler,¹ who in 1905 were led to the conclusion that the beneficial effect of graduated walking exercise in the sanatorium treatment of consumption was due to autoinoculation with small doses of tuberculin, which raises the level of the opsonic index. In one patient, who had a small, almost healed focus, walking exercise failed to elicit any rise in the opsonic index, and the indications in this case pointed to a total absence of autoinoculation.

Recently Paterson and Inman,² from an investigation of the effect of carefully systematized manual labour on the physical condition of consumptive patients and their progress towards recovery, as gauged by the range of temperature and the level of the opsonic index, concluded that graduated manual labour is directly beneficial to the able-bodied consumptive by reason of the repeated autoinoculations it induces, which find expression in a higher opsonic range. In 95 per cent. of the patients doing heavy manual work, Inman found the opsonic index to be above normal. A rise of temperature to 99° F. as a result of work is regarded as indicating a condition of hyperinoculation, calling for absolute rest. Obviously, manual labour will lead to autoinoculation when walking exercise fails to do so by reason of the more active respiratory and muscular movements to which it gives rise.

Walking exercise and graduated labour, therefore, are important and essential elements of the sanatorium régime, inasmuch as they represent an autoinoculation with tuberculin, the doses of which depends in susceptible cases on the amount of exercise and degree of labour. But autoinoculation as a specific measure has distinct limitations. It is not possible to exercise complete control over the dosage in all cases; moreover, patients treated in this way are inoculated, after a certain phase has been reached, with gradually decreasing doses of tuberculin, and indeed in quiescent cases autoinoculation may cease altogether. The clinical history of many of these cases indicates that this fails to elicit an efficient and lasting immunizing response, and if a high level is to be maintained it becomes necessary to supplement the failing autoinoculation by the introduction of tuberculin from without. The occurrence of relapse in patients who have derived material benefit from autoinoculation may frequently be traced to the failure of the organism to protect itself against a sudden hyperinoculation induced by physical strain, exhaustion, etc. Further, it is the experience of most sanatorium physicians that, other things being equal, patients treated with Koch's tuberculin are less liable to relapse than those in whom no such specific treatment has been employed. In a word, the employment of tuberculin in suitable cases in known and gradually increasing doses produces a marked and efficient tolerance which ensures a greater freedom from relapse. It is therefore suggested that in all cases in which the clinical evidence points to the absence of hyperinoculation and the possibility of a diminishing or absent beneficial autoinoculation, gradually increasing doses of Koch's tuberculin should be administered.

PHASES OF AUTOINOCULATION IN RELATION TO TREATMENT.

The degree of autoinoculation in pulmonary tuberculosis varies within wide limits. In quiescent and almost cured cases it may be entirely absent. In benign cases it is slight, and when the dosage is proportionate to the physiological needs of the organism it is directly beneficial by increasing the agglutinins and opsonins of the blood serum. Apart from the clinical phenomena due to acute disease or a coexisting septic infection we have two distinct types of

pulmonary tuberculosis. In the one, to which the great majority of sanatorium patients conform, a hyperinoculation induced by walking exercise or manual labour is expressed by a rise in temperature; whereas in the other, which embraces a small minority, the temperature under like conditions tends to a subnormal range. It has also been observed in consequence of treatment that certain patients of the reactive type merge through an afebrile phase into the subnormal type.

The following facts have been noted with regard to this subnormal type: Improvement in the local condition as indicated by the character and number of crepitations is more rapid. The effect of graduated labour and walking exercise, which is to reduce the temperature below normal, invariably coincides with a marked improvement in the general and local condition. Lastly, such patients rapidly develop considerable tolerance to Koch's tuberculin. Another suggestive fact, first observed by Latham,³ is that in certain febrile cases tuberculin administered by the mouth in small doses induces a fall in temperature. In several cases which I have under observation a very decided subnormal range followed the administration of tuberculin. Curiously enough, however, in other cases the same dose produced a rise in temperature. The effect seems to depend largely on idiosyncrasy and suitable dosage, although the possible influence of an associated pyogenic infection must be kept in view.

In studying the degree and extent of hyperinoculation in tuberculous patients, we find certain phases of inoculation which are dependent for the most part on the character and extent of muscular effort. In acute cases there may be a continued hyperinoculation during rest, the temperature reaching 99° F. or above it notwithstanding absolute rest in bed. This hyperinoculation may continue indefinitely, or yield to the influence of rest and appropriate treatment. The second phase is characterized by the absence of hyperinoculation during rest and its development as a result of muscular effort. The amount of exercise varies from a few steps to several miles a day, and its effect upon the temperature becomes a useful guide in estimating the patient's susceptibility to hyperinoculation, and likewise to the activity of the disease. The frequency and degree of hyperinoculation induced in this way varies in different cases, and also according to the length and gradient of the walk. As the patient's condition improves, a well-marked immunizing response is gradually evolved, and it becomes more difficult, and at last impossible, to induce hyperinoculation by walking exercise. Finally, in some cases a mean subnormal temperature is attained.

Manual labour may induce hyperinoculation when walking exercise has failed to do so, this being due to the more active muscular and respiratory movements it entails. The majority of patients, however, who are able to take the maximum amount of walking exercise along roads of varying gradient will be found capable of undertaking the heavier grades of manual labour without any injurious reaction. Occasionally a somewhat severe autoinoculation is induced, which, however, yields rapidly to rest and treatment. The absence or presence of susceptibility to hyperinoculation induced by manual labour is of some value in forecasting the ultimate results of treatment. The fact that a specified amount of manual labour under the ideal conditions of sanatorium life gives rise to hyperinoculation is of somewhat unfavourable prognostic significance, especially if it occurs in the case of the wage-earner who is compelled after a course of treatment to follow some arduous occupation. Conversely, the absence of hyperinoculation under like conditions is to be regarded as distinctly favourable.

In patients who are responding well to treatment a stage is reached when even an occasional hyperinoculation fails to occur. This is probably due to a relatively high immunizing response and a diminished tuberculin output. In such patients the temperature at 6 and 8 p.m. is normal or subnormal. Very occasionally it may reach 98.8° F. A temperature of 98.6° F. following walking exercise or manual labour should be regarded as the maximum compatible with beneficial autoinoculation. Even a somewhat frequent rise to 98.6° F. should be viewed with some misgiving. The most favourable indication in this stage is a tendency towards a mean subnormal temperature. In the majority of cases the

complete absence of hyperinoculation under all conditions is only attained after much patience and by gentle gradations.

Although it cannot be accepted as conclusively proved that every rise of temperature to 99° F. and above it in a patient suffering from pulmonary tuberculosis is due to a hyperinoculation with his own tuberculin, it is a wise and safe rule to assume that such is the case. The light which recent investigation has shed on the value of walking exercise and manual labour in the treatment of pulmonary tuberculosis has largely increased the importance of stringent medical supervision and widened the responsibility of the sanatorium physician. The daily routine as regards rest, walking exercise, and manual labour must be carefully mapped out for each patient, and the question of recreation calls for like careful consideration. This was specially emphasized by Latham some years ago. It is somewhat remarkable that certain patients are able to undertake heavy manual labour without any rise of temperature, and yet a game of cards, bowls, croquet, or chess is followed by a rise of one or even two degrees; in the majority of such cases the rise of temperature is probably of nervous origin, as it speedily falls to normal. Occasionally the rise persists, and is obviously due to a hyperinoculation from quickened pulse-rate. Such cases are not suitable for tuberculin treatment.

THE ROUTINE OF TREATMENT.

The following are the general principles underlying the treatment at present carried out in the Liverpool Sanatorium. In febrile cases (temperature 99° F. or above) the aim of treatment at first is to cut short the period of hyperinoculation, so as to hasten the relatively quiescent phase, when the amount of autoinoculation suffices to evoke an immunizing response and becomes directly beneficial to the patient. When hyperinoculation has entirely ceased under all conditions an effort is made to induce tolerance to relatively large doses of tuberculin by supplementing the beneficial autoinoculation which may be present with gradually increasing doses of Koch's tuberculin. The importance of avoiding a hyperinoculation is always kept in view.

Febrile cases are treated by absolute rest in bed and the administration of calcium lactate or calcium chloride with or without some antipyretic drug. In patients with a superadded septic infection some antiseptic form of treatment is employed. The diet is suited to the digestive requirements of each individual, large quantities of milk and in some cases gelatine moulds being given.

Patients with slight degrees of fever which have not yielded to the ordinary therapeutic measures (chiefly absolute rest) are, after a time, allowed to have walking exercise or are prescribed tuberculin in small doses by the mouth. It is a curious yet significant fact that in certain patients with slight pyrexia the autoinoculation induced by walking exercise or the administration of tuberculin in small doses by the mouth gives rise to a lower range of temperature, while in other patients under like conditions a higher range is produced. Unfortunately it is not possible to foresee what the result may be in any given case. The tuberculin may be given in very small doses thrice daily or in larger doses twice or three times weekly. In some cases it is prescribed in mixture along with calcium chloride. When tuberculin administered by the mouth has had a beneficial effect upon the temperature it usually produces a subnormal temperature, but not infrequently the chart shows an absolutely normal temperature, between 98° and 98.4° F. the well-marked amplitude which was previously present owing to a low morning remission having disappeared.

Walking exercise ordered with the view of reducing fever in patients with slight hyperinoculation must be very carefully employed. It is only in a few patients of a certain type that it proves beneficial. If the temperature rises it is doing harm and should at once give place to absolute rest.

When the absence of hyperinoculation during rest has been secured, graduated walking exercise is commenced as the next step in treatment. The walks are at first short but are increased by easy stages. Great care is taken not to prescribe too long a distance for the first few walks, as patients who have been some considerable time at rest are during the first few days very susceptible to hyperinocula-

tion. I cannot too strongly emphasize the importance of systematized and graduated walking exercise, more especially during the transitional stage between hyperinoculation during rest or that induced by movement, and the beneficial autoinoculation which subsequently results from exercise. When in consequence of walking the distance prescribed a rise of temperature to 98.8 or 99 F. results, the distance is shortened or the patient is ordered to rest. Perhaps the greatest difficulty is disobedience on the part of patients to instructions given. To meet this possible difficulty a few lectures are delivered to the patients from time to time on the general principles of treatment, and the importance and true value of walking exercise and graduated labour.

After a period varying from a few days to several weeks, according to the susceptibility of the patient, a stage is reached when the maximum amount of walking exercise is daily undertaken without any resulting hyperinoculation. Patients in whom this stage has remained unimpaired for a week or ten days are prescribed manual labour. The work is ordered not only as a means of inducing a further beneficial autoinoculation, but as a definite test. Broadly, it consists of two grades, medium and heavy, and includes weeding, trimming, moving, joiner work, digging, shovel work, barrow and pick work, etc. Experience has shown that the majority of patients who have been able to take the maximum amount of walking exercise without any rise of temperature or other evidence of hyperinoculation may safely be put to medium or heavy grades of work. From 9 a.m. to noon the patients work, and in the afternoon they are sent a long walk, as many when at work assume a stooping attitude. If the temperature rises in consequence of manual work the patient is ordered to rest for a day or two, after which he is put back to walking exercise until he qualifies again for manual labour.

The final stage in the treatment of male patients is the employment of inoculations with Koch's tuberculin in gradually increasing doses. This is begun when they have passed the test of a week or ten days' heavy manual labour without any resulting hyperinoculation, as indicated by a rise of temperature to 99 F., or an amplitude which exceeds one and a half degrees. The initial dose of tuberculin is $\frac{1}{1000}$ mg., according to the old dosage. Following the initial dose, an inoculation is given every week, the dose being gradually increased during the course of treatment; the maximum dose reached depending in each individual case upon the duration of the patient's residence in the sanatorium. The time for inoculation is the early afternoon, after which the patients rest for the remainder of the day. Patients rest or follow their usual routine, according to instructions, the day after. The injection is given alternately in the right and left interscapular regions under aseptic precautions. Every male patient who has passed the heavy labour test is inoculated in this way, and the experience of this method so far points very definitely to the fact that not only may tuberculin be given in increasing doses with absolute safety, but that in many cases it is followed by a lower range of temperature (that is, a mean subnormal temperature) and improvement in the local condition.

The female patients are treated by a somewhat different method. For obvious reasons, it is not possible to test them so thoroughly, nor is it desirable, as female patients are more susceptible to autoinoculation, and react more strongly to tuberculin than male patients. Further, with few exceptions, they shrink from the needle. The method adopted, therefore, is to test them for a week or ten days with long walks, some of considerable gradient, and if during that time no hyperinoculation has taken place tuberculin is given by the mouth in gradually increasing doses, the initial dose being $\frac{1}{1000}$ mg. Each patient must, of course, graduate for the long distance test by successfully passing through the intermediate grades of walking exercise.

Both male and female patients are carefully watched and tested regarding any increase of susceptibility to hyperinoculation in consequence of the administration of tuberculin either by inoculation or *per os*. As might have been expected, a slightly increased susceptibility has occurred in one or two cases. It was observed when the patient was tested by a long walk or some heavy manual labour on the day following the administration of tuber-

culin. In order to obviate as far as possible any increased tendency to hyperinoculation patients, on the day following the first administration of tuberculin, are allowed to rest or are prescribed a short walk or some light manual work. If this initial test be successfully passed, the same dose is given the next week, and the following day the patient is prescribed a long walk or some heavy manual work. If the temperature remain unchanged an increased dose is given the following week. Those cases in which hyperinoculation takes place are either treated with a smaller dose, followed by rest, or the administration of tuberculin is stopped altogether, and the patients are treated by autoinoculation alone for a further period of time. It is very necessary to avoid any constitutional disturbance, and therefore the rule is strictly adhered to not to increase the dose of tuberculin until the amount already given, *plus* the extent of autoinoculation induced by heavy manual labour in the case of males and distant walking exercise in the case of females, fail to produce a hyperinoculation.

During the past eight months 47 patients have been treated with tuberculin—31 males and 16 females; 28 male patients received 180 inoculations, the minimum dose being $\frac{1}{1000}$ mg., and the maximum $\frac{1}{100}$ mg. In all these cases the patients were first of all tested with walking exercise and heavy manual labour. The 3 remaining cases were treated with tuberculin by the mouth— $\frac{1}{1000}$ mg., divided into twelve doses, one dose thrice daily. It was given with the view of reducing slight persistent fever, and was continued for several weeks. In 2 of the patients the result was very striking; in the third case the patient left before any beneficial effect was observable.

Of the 28 male patients inoculated, 23 have left the sanatorium, all of them able to work. In only 2 were tubercle bacilli found in the sputum before leaving; 5 are still under treatment. Of the 23 discharged, tubercle bacilli were found on admission in the sputum of 16. The effect of the whole course of treatment upon the physical wellbeing and pulmonary condition in the case of these patients was very marked. An effort is being made to keep in close touch with all patients who have been under treatment, so that definite information may be obtained regarding the true value and ultimate results of this method of treatment compared with treatment by autoinoculation alone.

Of the 16 females, 2 were treated by inoculation, the remaining 14 having tuberculin administered by the mouth. In 7 of these cases there was slight persistent fever, and tuberculin was given in the hope that it would favourably influence the pyrexia. In five of the cases the effect upon the temperature was marked. Thus, in one case, during forty days prior to the administration of tuberculin by the mouth, the temperature had registered 99 F. or higher on seventeen occasions; whereas during a like period subsequent to the commencement of tuberculin treatment, it reached as high as 99 F. only on two occasions. In the case of a child, aged 11, who had been under treatment for several months suffering from a discharging sinus connected with hip disease and a swinging temperature, the effect of tuberculin by the mouth was to bring about the expulsion of two small sequestra, with complete healing of the sinus and an absolutely normal temperature. In two cases no beneficial result was obtained. In one of these the tuberculin was stopped as it induced an increased amplitude, with a somewhat higher range; the other patient left the sanatorium before any effect was observed. In the case of the seven remaining female patients tuberculin was administered in increasing doses after they had been thoroughly tested as to the absence of hyperinoculation. The initial dose was $\frac{1}{1000}$ mg.; all these patients are doing well.

As has already been stated, two methods of administering tuberculin by the mouth are employed. In the case of female patients in whom hyperinoculation is no longer induced by walking exercise it is administered weekly in gradually increased doses, usually beginning with $\frac{1}{1000}$ mg. and followed by $\frac{1}{1000}$ mg., $\frac{1}{1000}$ mg., and so on. When it is given with a view to control hyperinoculation and reduce slight grades of fever, $\frac{1}{1000}$ mg. is diluted with glycerine and sterile water and divided into twelve doses, one dose being taken three times in the day; occasionally $\frac{1}{1000}$ mg. is given in single dose every third day. Experience has shown that this method of dividing the doses is more effective in reducing slight degrees of fever.

With the exception of one patient who was treated with bovine tuberculin, Koch's new tuberculin was used in all the cases. In future tuberculin of bovine origin will be given a trial in a certain proportion of cases. This method of selection for treatment by tuberculin in cases of pulmonary tuberculosis has been found useful and practical. It is safe and easily applied in the ordinary routine of sanatorium work.

CONTUSION OF THE LUNG WITHOUT EXTERNAL INJURIES.

By ED. MARTEN PAYNE, M.B., C.M.ABERD.,

BLACKBURN.

As it appears to be incredible to some that contusion of the lung may result from an accident without visible signs of injury to the chest wall, I think it well, before describing a case which recently came under my observation, and which resulted in an action under the Employers' Liability Act, to cite some of the authorities upon which I based the opinions which I expressed, and defended in the witness box, in respect to it. That the condition is recognized by the Registrar-General as a cause of death is shown by the fact that the phrase "Contusion of heart or lung without wound" is included in *The Nomenclature of Diseases*.

W. J. Walsham, in his *Surgery*, says:

Contusion of the lung without an external wound may be produced by a severe crush or blow upon the chest. The visceral layer of the pleura may or may not be lacerated. . . . Pneumonia or abscess or gangrene of the lung occasionally ensue" (pp. 398-399, ed. 1890).

Erichsen in his *Surgery* (vol. i, p. 829, ed. 1884) says:

Contusion of the lung without injury to the pleura covering it may happen from severe blows on the chest, as from falls from horseback or kicks on the side. It may be complicated with fracture of one or more ribs; but this is not necessarily a concomitant of the injury.

Stonham in his *Surgery* (vol. ii, p. 324, ed. 1899) says:

Contusion and rupture of the lung may result from simple concussion of the chest.

And further (p. 327):

Slight localized pneumonia may result from simple injury to the lung with or without wound of the chest wall. In such cases the inflammation is very limited in extent, produces few physical signs and but little constitutional disturbance. It may, however, be very dangerous in the aged or enfeebled.

Holmes in his *Surgery* (p. 204) says:

In severe contusions of the chest . . . the lung is sometimes lacerated without the chest wall sustaining any visible injury.

Osler in his *Principles of Medicine* (p. 109, ed. 1901) says:

"Contusion-pneumonia." Pneumonia may follow directly upon injury, particularly of the chest, without necessarily any lesion of the lung. Litten gives 4.4 per cent., Stern 2.8 per cent.

Taylor, *Medical Jurisprudence* (ed. 1844, p. 292), says:

The lung may sustain serious injury from a blow or fall, and yet there may be no external marks of violence or symptoms indicative of damage for some hours.

Hoffman, *Atlas of Legal Medicine* (Plate 13), says:

A direct contusion of the lung occurs, especially in cases of fracture of the ribs, but is usually accompanied by laceration of the pleura, and even extensive laceration of the pulmonary parenchyma, but may take place without such associated lesions.

If, then, we can place any reliance upon classical authors, it appears that:

1. There is such a thing as "contusion of the lung."
2. The lung may be contused without being lacerated.
3. Contusion or laceration of the lung may occur without there being any visible injury to the chest wall.
4. The lung may sustain dangerous injuries, and yet no alarming symptoms may show themselves for some hours.
5. Contusion of the lung may give rise to a dangerous form of pneumonia.

I will now proceed to describe my case,

History of Accident and Illness.

On September 11th, 1908, I was requested by my assistant, Dr. Allan, to see, in consultation with him, a man named P. McV. I saw him at about 12.30 p.m. He was quite conscious, and gave me his own account of what had happened.

He told me that on September 8th he felt quite well, and went to his work at about 7 a.m. He came home to dinner at noon, and returned to his work still feeling quite well. The accident occurred at 3.30 p.m. He was working on a roof and fell over a spar or beam of some sort on his right side. Not feeling very seriously hurt at the time, he continued his work until about 5.30 p.m., when he went home. By this time the pain in his side was so bad that he went straight to bed. Fomentations and such home remedies were applied, and the man remained in bed, gradually getting worse in his breathing until the morning of September 11th, when, his friends getting seriously alarmed, at last sent for my assistant, Dr. Allan. He informed me that when he first saw the patient he was lying on his left side in bed. His breathing was shallow and quick, and he complained of great pain in his right side, towards the base of the lung. The temperature was 103°; respirations 35, and the heart small and irregular. The heart sounds were audible but distant; there was no bruit. There was dullness at the right base. The tongue was dry and foul.

When I saw the man, a few hours later, Dr. Allan remarked that his condition seemed to have slightly improved. The decubitus was exactly as above described, and the patient still had the pain in the right side, but he said it was not quite so acute. The temperature was 101°, and the respiration 35, and the heart sounds were difficult to count. The heart sounds were scarcely audible, and there was marked dyspnoea. I could find no signs of external injury to the chest, except redness and tenderness on pressure over a region towards the base of the right lung, where the patient complained of the internal pain. There was marked dullness on percussion in this region, and rales could be heard on both sides of the chest, especially towards the upper lobes. The tongue was furred, and the eyes were bloodshot and somewhat jaundiced. The general impression was a man in the second stage of pneumonia; the immediate anxiety was cardiac failure. The patient died at 2.30 p.m. the same day, exactly seventy-one hours after the accident.

In view of the recent accident I refused to give a certificate, and, by order of the coroner, the body was removed to the mortuary.

Necropsy.

An autopsy was conducted by my friend Dr. Bannister, in the presence of Dr. Allan and myself. There were no signs of injury to the thoracic walls, no ribs were fractured, there was no laceration of the soft tissues. The heart was flabby and light coloured.

Both lungs were more or less generally congested, and at the apices were a few very small scars, indicative of old healed tuberculous lesions. Extending inwards, from the surface of the lower lobe of the right lung, was a patch of red hepatization, about the size of the palm of the hand, and about one to one and a half inches thick. It was judged that this patch, *in situ* would just correspond with the spot indicated externally by the patient as being the place where the pain was so acute and continual, and where he had received the blow in falling. The liver, kidneys, and spleen were somewhat congested, and the coats of the stomach reddened.

Taking all the circumstances into consideration, I arrived at the conclusion that the man died of pneumonia; secondary to contusion of the lung, contracted by the accident. This also was the verdict at the inquest, on which occasion Dr. Bannister was the only medical witness called.

An action for damages against an insurance company followed. The case was tried on November 16th, 1908, at Blackburn County Court by Judge Hamilton, assisted by Dr. R. Hunt as medical referee. The contention was that the man died from pneumonia following contusion of the lung caused by the accident. I was the first medical witness called, and maintained this opinion, in which I was supported by Drs. Bannister and Allan.

The defence was that the pneumonia was due to natural causes, and was a mere coincidence, that it could not have been due to the accident as there were no visible signs of external injury. This view was supported by Drs. R. A. Gray and Walter Rigby, the only medical witnesses called by the defence. The judgement of the Court was that there had been an accident, that the man died of pneumonia, and that the accident had nothing to do with it.

I will now capitulate the grounds on which I formed the opinion that the pneumonia was the result of the accident.

1. The man goes to his work in the early morning feeling perfectly well, comes home to dinner, and returns to his work feeling perfectly well. He falls and hurts his side, not very badly, as he thinks, and manages to finish his job, which is not a very heavy one; but by the time he arrives home, after about two hours, the pain is so bad he

goes straight to bed. He gradually gets worse and worse and dies just seventy-one hours after the accident. Before he dies it is found that he is suffering from inflammation of that part of the lung which exactly coincides with the site of the accident. All this is confirmed by an autopsy. I find that many eminent medical and surgical writers assert that pneumonia may be caused by such an accident. I naturally conclude that the pneumonia was caused by the accident in the present case.

2. It is well known that pneumonia proceeds in three well-marked stages—congestion, red hepatization, grey hepatization. According to Hamilton, the stage of congestion lasts from twenty-four to thirty-six hours. The stage of red hepatization lasts from four to five days; moreover, the red stage is *crimson* red at first, and changes to a *granite* red as it is about to pass into the grey stage. Now, at the *post-mortem* examination the hepatization was crimson; it showed no sign of entering upon the grey stage. It seems, therefore, to be pretty certain that the patch of hepatization was not less than one or more than three days old. Now, if it was three days old, the man must have been suffering from pneumonia in the congestion stage for twenty-four or thirty-six hours *before* the accident; that is, all the time he was getting up early in the morning, returning to dinner, and doing his work, and feeling perfectly well, which seems to be highly improbable, to say the least of it. On the other hand, if the patch was only one day old, or less, then the pneumonia must have come on *after* the accident to which the man attributed the pain in the side, in which case it seems difficult to deny that the accident had anything to do with it.

Having given my reasons for connecting the origin of the pneumonia with the accident, it is now necessary to answer the main objection raised by the defence, namely, that it would be impossible for the lung to be injured by an accident which did not at the same time cause serious visible injuries to the chest walls.

The most striking answer to an objection of this sort is a case in point. Taylor² quotes the following case from the *Lancet* (November, 1842).

A young man, while riding, fell from his horse on his left arm. He complained of no pain for five hours, but in twelve hours he was seized with an alarming flow of blood from the mouth. He died in the course of a few days. After death there were no marks of injury to the chest, but the right lung was ruptured posteriorly throughout its length and much blood had become extravasated.

As it appears to be difficult for some to believe that there can be contusion of the lung without injury to the chest wall, I have endeavoured to find what has been written on the mechanism of this condition. The only author to whom I have access who has written anything on this subject is Hoffman. He says (*loc. cit.*):

A direct contusion of the lung occurs especially in cases of fracture of the ribs; but is usually accompanied by laceration of the pleura and even extensive laceration of the pulmonary parenchyma, but may take place without associated lesions.

Most frequently, however, such lesions appear to develop indirectly—that is, not at the place where the force was applied, but at some distant point, thus: from the part of the lung which becomes suddenly compressed by the external force the air and the blood contained within the vessels are suddenly driven towards the peripheral parts of the lung. There thus results a more or less extensive laceration of the lung tissue with hæmorrhage and interstitial emphysema.

Now, although this explanation appears to be partially correct, more especially in respect to the effect of blows upon the chest, upon the air in the lungs, it does not, in my opinion, take into sufficient consideration the effect of gravity upon the blood and tissues in the case of falls.

As this appears to be a very important subject, I venture to give the results of some experiments I have made.

Let us first consider the effects of gravity upon the blood stream.

We know that when a body falls its velocity continually increases, according to a certain law, until it reaches the ground. The formula is:

$$v^2 = 2gh.$$

where

v = the velocity, in feet per second.

g = the effect of gravity = 32.2.

h = the height from which the body falls.

If a man falls on his side from a height of only 4 ft.,

when his body touches the ground it will have attained a velocity of more than 16 ft. per second:

$$v^2 = 2gh.$$

$$= 2 \times 32.2 \times 4.$$

$$= 257.6.$$

$$\therefore v = \sqrt{257.6} = 16 \text{ approximately.}$$

That is to say, the velocity would be nearly twelve miles an hour, so that the blow would be equivalent to what the man would receive if he were struck by a tramcar running at full speed.

According to Volkman and Vierdosh³ the blood in the large arteries near the heart flows normally at the rate of about 10 or 12 in. per second, and at about 2½ in. per second in the arteries of the foot. We may, therefore, assume that the blood normally moves in the vessels of the lungs at the rate of not more than 1 ft. per second, and that in the arteries it flows towards, and in the veins from, the periphery.

During the fall this state of things continues relatively, that is, if we regard the blood stream with relation to the body, but they are not the same absolutely, that is, if we regard the rate and direction of the blood stream in relation to the ground, towards which the body is falling.

During the descent the blood acquires a velocity, with regard to the earth, of 16 ft. per second. But the blood in the arteries running towards the surface of the lung has already at the commencement of the fall an intrasomatic velocity of 1 ft. per second, which must be added to the velocity accrued by the fall, making a total of 17 ft. per second. On the other hand, the initial intrasomatic centripetal velocity of the blood in the pulmonary veins must be deducted, making the sum of 15 ft. per second.

Now, as already indicated, during the fall these changes in the velocity of the blood in respect to the earth have no effect on the body, because the velocity of the whole body is increasing in a like ratio, just as, when we are travelling in an express train, our blood may be travelling at the rate of 100 miles an hour but we feel no difference, because the whole body is travelling at the same rate. When the fall is arrested, however, the relations of things are instantly changed. The solid elements of the body are brought to a sudden state of rest, while the blood, being a fluid, continues to press onward with its accelerated velocity. Now this sudden change in the relative velocity and, in the case of the pulmonary veins, of direction of the blood stream must have a disastrous effect upon the capillaries at the periphery of the lung. Not only are these organs suddenly engorged on the arterial side by a flow of blood of seventeen times the normal velocity, but that flood, instead of finding its escape through its accustomed exit, is met by another flood, of almost an equally high velocity, forced back through the pulmonary veins. It seems impossible that the wall of these delicate organs could escape rupture.

Let us now consider the effects of the fall and its sudden arrest upon the solid structures of the thorax and its contents.

The thorax is a sort of bony cage, bound together and lined by muscles, fascia, etc. All these materials being highly elastic, the chest walls are capable of sustaining considerable stress without fracture of the ribs or break in the continuity of the soft tissues. The intrathoracic organs, which for our present purpose we may regard as one mass, are attached securely but not rigidly in their position, mainly by the trachea and great vessels and other organs and tissues of the neck and by the walls of the anterior and posterior mediastina. That the attachments are elastic enough to allow of considerable lateral movement is proved by the fact that in cases of left pleuritic effusion the heart may be pushed so far to the right that the apex beat may be found well to the right of the sternum.

During the fall the velocities of the thorax and its contents increase equally; but when the wall of the chest suddenly stops on reaching the ground the intrathoracic organs endeavour to continue in motion, and the surface of the lung is flung upon the pleura costalis, being at the same time compressed by the weight of the rest of the intrathoracic organs straining to overcome the resistance of their somewhat elastic attachments. The intrathoracic organs and the blood they contain cannot weigh less than 5 or 6 lb.—say 5 lb.; but $5 \times 16 = 80$, so that the momentum acquired by the fall would equal 80 ft. lb. What would be

the net effect of this impulse upon the surface of the lung I cannot say, but it would not be a negligible quantity. Probably the greatest danger from this source would be the stress upon the organs forming the attachments.

Of far greater importance, in my opinion, is the effect upon the surface of the lung of the impulse due to the fall of the body and conducted through the chest walls at the place of impact. These walls consist of a series of elastic bony rings, bound together by soft tissues.

If a ring made of an elastic material falls from a height, having its plane perpendicular to the earth's surface, what effect has the momentum acquired by the fall upon a body resting upon its inner circumference at the point opposite to the point of impact?

Let A B represent a wire tightly stretched and fixed perpendicularly between a point, A, in the ceiling, and another point, B, in the floor of a room. Let B D F be an iron ring, having an external diameter of 12 in. and an internal diameter of 11 in. Through the circumference of the ring, at opposite extremities of the diameter, B F, are holes, through which the wire, B A, passes, so that the ring can be drawn up to any desired height along the wire, and allowed to fall freely to the ground.

Let C be a ball of porcelain, or any hard substance, having a hole through it, through which the wire passes, so that it also is free to move up and down upon the wire within the iron ring.

Now, without lifting the ring B D F, raise the ball C as far as it will go along the portion of the wire B F, and let it fall.

It will be observed that, owing to the momentum which it has acquired in falling, it perceptibly rebounds, but not very much.

Next, without touching C, raise the ring B D F along with it until C is about a foot above the ground (that is, about as high as it was raised separately in the first experiment) and let the whole system fall freely to the ground. It will now be observed that the ring itself rebounds but little, but that the ball C will rebound, probably the whole diameter of the ring, proving that a large portion of the momentum acquired by the weight of the ring and the ball taken together has been reflected by the floor, passed through the rim of the ring, and expended in raising the ball C. The exact height to which the ball is raised depends chiefly upon the following conditions:

- The weight of the ring;
- The weight of the ball;
- The modulus of elasticity of the materials of which the ring and the ball are constructed; and, lastly,
- The height from which the ring and ball fall.

Taking the case of an iron ring weighing 12 oz. and a piece of porcelain weighing 2 oz., I calculate that about one-quarter of the momentum generated by allowing the system to fall 1 ft. was expended in raising the porcelain $9\frac{1}{2}$ in. It is obvious that if the weight of the ball is known, the height to which it rebounds is a measure of the momentum passed through the ring, minus the momentum which the ball itself has acquired during its fall, and which begins to exert itself independently and in a direction contrary to the reflected force, the instant the ring touched the ground. For although the ring and the ball during their fall are not physically one, they are acting in strict partnership during that time, and the whole of the momentum which they generate is communicated to the floor when the ring touches it; at that instant, however, the partnership is dissolved by the momentum of reaction passing through the ring, which, in acting on the ball, has not only to impart it an initial velocity sufficient to raise it to the given height, but also to overcome the effect of its own momentum downwards which it acquired in its fall, and which continues for a moment after the dissolution of its partnership with the ring.

It is needless to say, the intensity of the rebound varies with the height of the fall: thus, when the ring was lifted

about 3 ft., not only did the ring itself rebound, but the porcelain struck the opposite side of the rim with such force that it was fractured.

The point upon which I would lay especial stress is, that the amount of force impinging upon that part of the porcelain ball contingent to the rim of the ring, consequent upon the impact on falling, depends not so much upon the weight of the ball as upon the weight of the ring and ball taken together.

The general application of the dynamic principles I have endeavoured to illustrate, to the case of an injury to the lung resulting from a blow or fall upon the thorax, is obvious. It is true that the modulus of elasticity of a rib with its coverings differs from that of an iron ring, but it must be very considerable, especially in the case of a strong middle-aged man whose bones are hard. If such a man fell heavily upon his chest, and the ribs did not fracture, a large part of the momentum generated by the weight of the body and the fall would undoubtedly be conducted through the chest wall, and, impinging upon the surface of the lung, damage it considerably, even if it did not cause the rupture of the organ, as happened in the case quoted from the *Lancet* above.

Now note a seeming paradox—if the ribs are fractured the danger to the lung may be less.

For the iron ring on the wire was substituted one of wood. Inside the ring was strung a piece of porcelain, as in the previous experiments, the holes through the ring for the wire being drilled parallel to the grain of the wood. When the ring and the porcelain were raised to a moderate height and allowed to fall the porcelain rebounded energetically, as it did in the case of the iron ring, and the rebound was a measure of the amount of force conducted through the ring at the moment of impact. The ring and the porcelain were now raised to such a height that the momentum on falling was sufficient to fracture the ring. In this case, although the ring was fractured, the porcelain rebounded but little, showing that it was but little affected by the force of impact.

As the result of many experiments with wooden rings I have arrived at the following conclusions:

Each ring has a coefficient of fracture of its own, so that of two similar rings, one does not fracture as easily or in exactly the same manner as the other. This results from small differences in hardness and direction of grain, etc.

A ring does not fracture easily, and the porcelain rebounds but little, if the holes through which the wire passes are drilled, not parallel to, but across the grain, showing that the force is conducted more easily along the fibro-vascular bundles than across a fasciculus of such bundles.

The phenomenon is also accounted for partly by the fact that a wooden ring is more easily flattened or rendered ovoid by a force applied at right angles to the grain, than by a force applied parallel to the grain, and that the force expended in flattening the ring does not pass through it. For example, two small wooden rings were compressed in a vice, until they fractured: in the first case the force was applied parallel to the grain, and fracture occurred when the diameter had been reduced 2 per cent.; in the second case the force was applied across the grain, and the diameter was reduced more than 10 per cent. before the ring suffered fracture.

If a ring be taken, having one of its sides already fractured, and the holes be drilled parallel to the grain:

(a) If the fracture is on the upper side of the ring, the ring on falling will be fractured on the lower side, and the porcelain will not rebound.

(b) If the fracture be on the lower side of the ring, so that the porcelain is resting on the fracture, the ring on falling may suffer no further fracture, but the porcelain will not rebound.

I therefore conclude that rings which are compressible in the direction of the force applied, or rings which are fractured, conduct the force of impact less readily than rings which are whole and less compressible.

Applying these results to the case of the ribs, I conclude as follows:

If the ribs are soft and pliable, as in the case of young persons, they are less liable to fracture, but, as they bend, the force expended in bending them is absorbed, and therefore does not so easily pass through them and injure the lung.

If the ribs are hard, as in elderly persons, they are more liable to fracture. If they do not fracture, on account of their hardness, a large part of the force applied is conducted through their substance to the detriment of the lung. If they do fracture, the force producing this result is saved from the lung.

It may thus happen that a greater fall may be less dangerous than a lesser one, for, if the fall be just sufficient to break the ribs, but little force will pass through them and there will be less danger to the lung. On the other hand, if the fall be just not sufficient to fracture the ribs, a large part of the force accrued by the fall will pass through the chest wall and there is danger of contusion of the lung.

These results appear to be in agreement with clinical observation, fatal contusion of the lung being of more frequent occurrence in elderly than young persons.

It is needless to say we are not here considering those cases in which the substance of the lung is penetrated by a fractured rib.

Space will not allow me to discuss fully the interesting question whether the consolidation found in cases of contusion of the lung is identical with that of ordinary croupous pneumonia. I will content myself by stating that there are two opinions on this point. The first is that the portion of the lung contused is rendered a suitable nidus for the pneumococcus, and that ordinary pneumonia results. The second is that the solidification is simply due to the coagulation or "organization" of the blood poured into the air cells as the result of the contusion. As Hamilton⁴ says: "It must be remembered that there are pneumonias and pneumonias; that a croupous exudate may be poured into the lung through a multitude of exciting agents, and may even result from purely mechanical causes which lead to embarrassment of the pulmonary circulation."

A NOTE ON BODY-WEIGHT IN RELATION TO PULMONARY TUBERCULOSIS.

BY

F. PARKES WEBER, and W. R. KIRKNESS,
M.D., F.R.C.P., M.R.C.S., L.R.C.P.,

SENIOR PHYSICIAN TO THE
GERMAN HOSPITAL, LONDON,
AND PHYSICIAN TO THE
MOUNT VERNON HOSPITAL
FOR CONSUMPTION, HAMPESTEAD.

LATE ACTING RESIDENT
MEDICAL OFFICER, MOUNT
VERNON HOSPITAL FOR
CONSUMPTION, HAMPESTEAD.

It is generally acknowledged (and to some extent acted on in regard to life assurance) that, both in families in which there is supposed to be a predisposition to tuberculosis and in those in which there is none, the overweight members are less likely to develop consumption than the underweight members. C. L. Greene¹ quotes the combined experience of the Washington and National Life Assurance Companies (3,548 cases), showing that in persons apparently without special predisposition to consumption the percentage of deaths from consumption was 5.20 for weights above the standard, 15.67 for standard weights, and 24.20 for weights below the standard; whilst in persons supposed to have a predisposition to consumption the percentage of deaths from consumption was 5.59 for weights above the standard, 25.91 for standard weights, and 42.51 for weights below the standard. Greene² likewise quotes the experience of the Connecticut Mutual Life Insurance Company (1846 to 1895 inclusive), showing that the percentage of deaths attributed to tuberculosis was 22.0 in underweights and only 1.9 in overweights.

C. Muirhead, when studying the causes of death among the assured in the Scottish Widows' Life Assurance Society (1874 to 1894 inclusive), looked up the height and weight as tabulated on admission into the life assurance society (1) of 524 males who ultimately died of pulmonary tuberculosis; (2) of 502 who were said to have died of "apoplexy." Amongst those who died of apoplexy, 59.87 per cent. weighed, on admission for life assurance, above the normal standard for their height and age (as calculated according to Dr. W. Robertson's standard table),

and 40.13 per cent. weighed below the standard; whilst of those who ultimately died of pulmonary tuberculosis only 19.30 per cent. weighed on admission above the standard, the large proportion of 80.70 per cent. weighing below the standard.³

We wished to ascertain as far as possible what the average weight of consumptive patients in a large hospital for consumption was (1) in comparison to their height and (2) in comparison to the average of their former ordinary weights.

In the Mount Vernon Hospital for Chest Diseases it is the rule to enter the height and weight of every patient on admission, and likewise to note what the former ordinary weight was whenever information on that subject can be obtained.

We determined, therefore, with the consent of the medical staff, to collect these data from cases in which the former ordinary weight was mentioned.

(A) In a series of 500 male patients 25 years old and upwards, all of whom had tubercle bacilli in their sputum, we found that the average height was exactly 5 ft. 7 in.; that is, the figure obtained by adding together the heights of all the patients, as entered in the notes on admission, and dividing by 500. Their average weight on admission, obtained in the same way, was 9 st. 1 lb. 13 oz.: 53 of them (10.6 per cent.) weighed more than 10½ st., 3 (0.6 per cent.) weighed exactly 10½ st., and 444 (88.8 per cent.) weighed less than 10½ st. The average of their former ordinary weights was 10 st. 5 lb. 9 oz.: 204 of them (40.8 per cent.) used to weigh more than 10½ st., 16 (3.2 per cent.) used to weigh 10½ st., and 280 (56.0 per cent.) used to weigh less than 10½ st. It seems, therefore, that the average of the former ordinary weights of these male patients (presumably their weights as far as they knew before their illness) was below standard, though of course not so decidedly "underweight" as their average weight on admission was.

(B) In a series of 100 female patients 25 years old and upwards, all of whom had tubercle bacilli in their sputum, we found that the average height was exactly 5 ft. 3½ in., that is, the figure obtained by adding together the heights of all the patients, as entered in the notes on admission, and dividing by 100. Their average weight on admission, obtained in the same way, was 7 st. 9 lb. 13 oz. Eighteen of them weighed more than 8½ st., 1 weighed exactly 8½ st., and 81 weighed less than 8½ st. The average of their former ordinary weights was 8 st. 8 lb. 12 oz. Fifty-four of them used to weigh more than 8½ st., 1 used to weigh 8½ st., and 45 used to weigh less than 8½ st. It seems, therefore, that though the average weight of these female patients on admission was much below standard, the average of their former ordinary weights (presumably their weights as far as they knew before their illness) was scarcely below standard, certainly not so "underweight" as that of the male patients (Series A).

(C) We likewise collected similar data from a series of 100 male patients in their 30th year or upwards, who whilst they were in the hospital presented undoubted physical signs of old pulmonary tuberculosis, though they had no fever and no tubercle bacilli in their sputum (patients in whom, in fact, the tuberculosis appeared to be quiescent or not very active). Their average height was 5 ft. 6½ in. Their average weight on admission was 9 st. 7 lb. 5 oz. Twenty of them weighed more than 10½ st.; 3 weighed exactly 10½ st.; and 77 less than 10½ st. The average of their former ordinary weights was 10 st. 6 lb. 11 oz.; 48 of them used to weigh more than 10½ st., 1 used to weigh 10½ st., and 51 used to weigh less than 10½ st. It seems, therefore, that the average weight in this series of male patients on admission and the average of their former ordinary weights were both below standard, but not so much so as in the series of male patients (Series A) showing signs of active pulmonary tuberculosis and having tubercle bacilli in their sputum on admission. This may be taken, perhaps, to signify that a generally more robust habit of body accompanied their resistance towards tuberculosis, a resistance shown by the relative quiescence of the disease.

Probably the preference shown by pulmonary tuberculosis for "underweights" would have been more strikingly illustrated by our cases had it not been that

consumptive patients, on admission to hospitals, when the case notes are being taken, are inclined to exaggerate their loss of weight—that is to say, there is a tendency for them to overestimate their former ordinary weight.

Our results have been classified in the accompanying table.

ASTHMA: ITS CAUSATION AND TREATMENT.*

By WILLIAM LLOYD, F.R.C.S.Ed.,

LONDON.

AMONG the various chronic complaints to which the human frame is liable, very few can be considered of a more formidable nature than a confirmed asthma. The idea of its being an incurable disorder, its threatening instant suffocation at every attack, are circumstances altogether so alarming to a patient as necessarily to weaken and depress a mind endowed with the utmost fortitude and resignation. Any remedy, then, whether medicinal or surgical, that is capable of administering permanent relief to a person in such an afflicting situation, must be looked upon as of the utmost importance to mankind.

It may be stated that to-day a radical cure can be promised in a large percentage of cases, especially if asthma is treated in its early stages; of the remainder a number can be relieved altogether for the time, though they may be subject to subsequent attacks.

CAUSATION.

Although it would be idle to deny that the seeds of asthma are sometimes transmitted from parents to their offspring, yet too much pains have been taken by past writers to persuade the world that this is most commonly the case.

This opinion, as far as I am able to judge, was founded on the inefficacy of the remedies generally employed, rather than on the more faithful and unerring testimony of observation. Physicians supposed, as the disorder seldom or never yielded to the power of medicine, that some hidden and unconquerable cause had fixed its roots deep in the constitution, and as an apology for the healing art they have thought proper to charge this to the account of an hereditary taint. Happily, however, we know that in the large majority the case is otherwise. As an example of the hereditaryness of the disease I will describe an interesting case that came under my notice in the summer of last year.

A lady consulted me in June, 1907, and brought her eldest son, who was 22 years of age, suffering from asthma. The family history is briefly as follows: Mrs. E., the mother, aged 51, married twenty-seven years ago, her husband being typically asthmatic. Two children were born of this marriage, both boys. Asthma in each case commenced at two years of age. The father died when the eldest boy was 7 and the youngest 5 years of age. Two years later the mother married again, this time not as an asthmatic. Of this marriage there are three children, the eldest being in his 16th year, perfectly free from any suspicion of asthma.

From this fact (if a solitary case can have any weight) it may be inferred that the predisposition is inherited.

There are numerous theories as to the causation of asthma, but, in my opinion, the only one which can be successfully maintained in the present state of our knowledge is the following: That asthma is essentially a nervous disease, and that it is due to spasm of the bronchial muscles, induced reflexly either by irritation of the nasal mucous membrane or of the alimentary canal.

To state my point clearly, take a case of asthma of nasal origin (fortunately they are the commonest), wash the patient's nose out with a mild antiseptic lotion—boracic acid, for instance—and in ninety nine cases out of a hundred you will produce an attack of asthma, which is immediately cut short on the application of a 10 per cent. solution of cocaine to the nasal septum in the region of the anterior end of the middle turbinate. In cases of hay asthma and ipecacuanha asthma, the excitant of the paroxysm is something applied to the nasal and not the bronchial mucous membrane. Of this fact I have convinced myself by a simple experiment. Plug the nostrils, and allow the patient to inhale pollen or ipecacuanha through the mouth, and invariably he remains free from any suspicion of asthma.

It would appear, then, that there are three factors in the causation of asthma, namely:

1. The presence of hypersensitive areas in the nasal mucous membrane, or a special sensitiveness of the gastric mucous membrane.
2. A special irritability of the pulmonary nervous system, which constitutes the asthmatic idiosyncrasy with which the individual was born.
3. The presence of an irritant—for example, odours, dust, smoke, etc. Error in diet when of gastric origin.

The absence of any one of these factors is sufficient to prevent the disease.

TREATMENT.

The remedies that have been generally made use of in this disease are of great variety, such as expectorants, antispasmodics, etc.; but, like that of all paroxysmal affections, it naturally divides itself into the treatment of the paroxysm and the treatment in the intervals.

The first thing to be done on being summoned to a patient in an attack of asthma is to find out if there is any exciting cause present, and if so to remedy it. Inquire as to the time and digestibility of the last meal, and if his bowels are free and regular; if there be any source of trouble in the stomach or rectum, secure its immediate removal. If there is anything irritating in the air he is breathing, arrangements must be made for removal. If the patient is in bed, get him out and bolster him up in an arm-chair, place before him a table with a cushion on it, on which he may rest his elbows and throw himself forward.

Should the paroxysm persist in spite of these measures, then one of the following remedies must be administered in the hope of cutting it short. I have occasionally found ipecacuanha powder cut short an attack for the rest of the night. The use of pipe tobacco smoking acts admirably in some patients. It must be remembered that remedies of this kind must be given as early as possible, because

* Read before the Chelsea Division of the British Medical Association.

it is just easier to check the asthmatic paroxysm when it is much established.

One of the commonest and most effectual remedies is coffee. It acts better if given very hot and strong and without sugar and milk.

Alcohol, chloroform, and cocaine are remedies of the value of which I have often seen most striking instances in checking an attack however severe. One feels great unwillingness to commence these drugs; still, in face of the frightful agonies of asthma and the uselessness of every other remedy, one is perhaps justified in prescribing one or other of them when the occasion demands.

Shrámionum smoking and inhalation of the fumes of burning nitre paper are remedies also extremely beneficial in some cases.

Potassium iodide is a remedy that, in the opinion of many physicians, is considered almost a specific. I regret to say that in my own experience very little permanent relief has been obtained after a long course of the drug.

It has been stated by many competent practitioners that careful dieting cures a large proportion of asthma because its victims are very often dyspeptics. The food should be nutritious and easily digestible, should be plain, well cooked, and containing the proper proportion of animal and vegetable elements. An important point to remember is that an asthmatic should dine early—5 p.m. is the latest if he goes to bed at 10—so as to allow of digestion being completed and the stomach empty before retiring to rest.

If in the nose some disease or deformity is present likely to cause asthma the condition must be rectified. Where no disease is present on inspection certain parts of the nasal mucous membrane, known as asthmogenic areas, must be cauterized, one by one, at several sittings until improvement is effected.

In prescribing a lotion for nasal cleansing I would point out that nothing acts so well as a solution of common salt in water. The various proprietary nasal compounds on the market containing boracic acid, carbolic acid, etc., are particularly irritating to the nasal mucous membrane of an asthmatic.

A CASE OF PANCREATIC DIABETES ASSOCIATED WITH DILATATION OF STOMACH FOR WHICH GASTRO-ENTEROSTOMY HAD BEEN PERFORMED.

By J. SOUTTAR McKENDRICK, M.D., F.F.P.S.G.,
F.R.S.E.,

SENIOR DISPENSARY PHYSICIAN, GLASGOW WESTERN INFIRMARY.

THE following case is of interest, as it affords an example of the class of cases recently referred to by Mr. Mayo Robson in his Mitchell Banks Memorial Lecture on the anatomy of the pancreas in relation to its diseases, where the disease, in the first instance, produced a dilatation of the stomach which was relieved by gastro-enterostomy, and, in the second instance, by invasion of the pancreas, caused definite signs and symptoms of acute diabetes.

J. McD., aged 46, a lamplighter, was first seen by me in the dispensary in June, 1903, complaining of weakness in the legs, great thirst, and the passing of large quantities of water, of three months' duration, and of indigestion and constipation for nine years.

History.

The patient in his youth had measles, scarlet fever, and enteric fever. When 15 years old he had an attack of rheumatic fever, followed by another similar attack at 28; but, apart from this, he had always been strong and well until nine years ago, when his stomach began to trouble him. He commenced to lose flesh, suffer from constipation, and had difficulty in eating and sleeping. This continued for a few years until he saw Dr. Mayland in 1902, who has kindly given me a few notes of the patient's condition while under his care in the surgical wards of the Victoria Infirmary of Glasgow.

Ten months previous to his admission he had an attack of influenza, which confined him to bed for a fortnight. After this he was troubled more than ever with flatulence, sourness in the stomach, flushing of the face, loss of appetite, and bodily weakness. He had to give up work, and for six months his tongue was always foul, and he was steadily losing in weight. There was never pain in the stomach nor vomiting.

Condition in 1902.

The patient was thin, the face flushed, teeth good, tongue-furred. The heart and lungs were normal.

Abdomen.—Seems normal in appearance. There is, however, marked tympanicity over the epigastrium and left hypochondriac regions, and Hippocratic succussion is present. No tenderness anywhere, and no dullness can be made out. The liver is not enlarged. The stomach was washed out and inflated. It was dilated, especially towards the left side, and extended downwards towards the umbilicus.

Urine.—The urine was neutral, with specific gravity of 1024, and contained neither albumen nor sugar.

A test breakfast was ordered after washing out the stomach, and 24 oz. of brownish fluid were drawn off. The fluid contained free HCl and amorphous semidigested fluid starch-matter.

Four days after admission a laparotomy was performed.

Operation.

After opening the abdomen the stomach was found to be dilated, and the pylorus appeared normal. The internal surface of it was examined digitally and by the speculum. The index finger passed easily through the pylorus without any sense of constriction. The mucous lining seemed quite healthy. A posterior gastro-jejunostomy was performed. In a few weeks the patient was dismissed from the infirmary well.

After-history.

The operation was not attended with the usual satisfactory results, and the weight, which was only 83 st. before the operation, did not quickly increase the patient's weight averaged 11 st. before his stomach commenced to trouble him).

In three years his weight had increased to 10 st., and had remained stationary until December, 1907. At this date he remembers getting a chill which was followed by what his doctor called "catarrh of the stomach." Soon after, however, in January, 1908, diabetic symptoms manifested themselves.

He commenced almost suddenly to experience symptoms that he had never had before—great thirst, foul-smelling faecal evacuations, and the constant passing of large quantities of water. With this there was marked prostration and loss of weight. The bowels were constipated, the motions yellowish, and sometimes sticky in character, and at other times slimy and "mattery." The tongue and mouth became dry, the skin cold, the legs swelled occasionally at the ankles, the taste in the mouth was sweetish. He noticed that the water was frothy, and had a sweet, sickly smell. The eyesight was not so good as formerly; deafness and tinnitus were troublesome. He had been troubled too, with itching of the skin. He had never had jaundice, vomiting, haemoptysis, or melaena. The legs felt very tired, but he had never felt numbness or pricking sensations.

Condition in June, 1908.

The patient is very thin, with a bright expression. The mucous membranes are rather pale. The finger ends are not clubbed, nor are the nails curved. The pupils are equal, and respond to light and accommodation. The tongue is furred, but on its under surface and at the sides it is red and glazed. The throat and palate are very red. Teeth not good, but no suppurative at the stumps. Pulse regular and of moderate tension. Vessels slightly atheromatous; no oedema; no jaundice.

Lungs.—Normal in every respect.

Heart.—Normal in every respect.

Nervous System.—Pupils normal, fundus normal; no catarract, knee-jerks sluggish; no anaesthesia, no ulcers.

Abdomen.—General fullness of abdomen. Scar of operation wound seen to right of middle line. Liver and spleen normal. Kidneys not felt. No ascites. Stomach passes down below the umbilicus (auscultatory percussion). No dullness, no thickening, or tumour of the pylorus or neighbouring parts. Succussion present. Palpation of the pancreas, by throwing forward the epigastrium, is negative. Bismuth meals were given to the patient on an empty stomach, and the shadow on the photographic plates (taken by Dr. Sommerville) corroborated what was already made out on physical examination, that the stomach was dilated to a point below the umbilicus. These plates failed to show any evidence of biliary or pancreatic calculi.

Urine.—A special examination of the urine by Dr. Cairns Douglas showed that it was very pale, feebly acid, specific gravity 1027, with scanty whitish deposit. It contained no albumen, acetone, or diacetic acid; no bile pigments or salts, pus or blood; no evidence of urobilin, although uroserin appeared to exist as a chromogen; diminished indigens; scanty creatinin; microscopically a few flat epithelial cells, and some phosphatic crystals; urea scanty, only 4 per cent., or 1.7 grains per ounce. Sugar, 8.7 per cent., or 38 grains per ounce. A positive Cambridge reaction after separation of all substances that might interfere with the test.

Blood.—Haemoglobin = 60 per cent.; red cells = 4,850,000; white cells = 4,750. Films of the blood were stained in 2 per cent. methylene blue solution and 25 per cent. eosin solution—the red blood corpuscles did not take on the eosin colour sufficiently (Bremer's test: 20 c.cm. of blood, 1 c.cm. of a watery solution of methylene blue (1 to 6,000), and 40 c.cm. of liquor potassiae was mixed in boiling water for four minutes. The blue colour disappeared into a dirty greenish-yellow colour (Williamson's test).

Habits.—Always abstemious. Smoked and chewed tobacco heavily until seven years ago. Never had any venereal disease.

Family History.—Father and mother are both alive and well. He has been married for twenty-two years and has three healthy children. He has always been well looked after.

This case presents many points of interest. The patient had dilatation of the stomach with no pyloric obstruction, and at a later date diabetes mellitus appeared. Have these two diseases any connexion with each other, or has the diabetes only occurred with dilatation of the stomach as a coincidence?

I should like to show, as has already been pointed out by Mr. Mayo Robson, first that in all probability in this case the stomach affection depended primarily on pancreatic disease, and, secondly, that the diabetes which followed depended upon a still further advanced stage of the pancreatic process.

At the time of the gastro-enterostomy it was found that the dilatation of the stomach did not depend on pyloric ulceration or tumour. It must have been due, then, either to primary atony of the stomach wall or to stricture or pressure on the duodenum at some distance below the pylorus. The fact that the patient was always a healthy man before the onset of the stomach trouble and had never suffered from neurasthenia is rather against simple atony. Granted that the duodenum was at fault, what affections could produce sufficient signs of pressure to cause secondary gastric dilatation? Ulcer could do so, with subsequent cicatricial contraction; but in such a case the patient would have had symptoms of pain in the epigastrium, and possibly melaena, which were entirely absent in this case. Cancer might do so, but that diagnosis could be easily excluded by considering the duration of the illness and the absence of physical signs. In both these conditions of the duodenum the pancreas could have been secondarily affected, giving rise to a new set of symptoms depending on pancreatic disease. These possibilities I think can be excluded.

The only other cause of duodenal stricture is pressure from without. The duodenum may be pressed upon by tumours in the abdomen, or may have its calibre interfered with by strands of coarse fibres depending upon old-standing inflammations with adhesions. In the patient under consideration, from the history and from the physical examination, there was no evidence of any liver, omental, or peritoneal disease, nor was the gall bladder at any time enlarged. Diseases of the pancreas, however, could cause pressure against the duodenum; but abscesses, cysts, and tumours of that organ would have manifested themselves by physical examination.

We are left, then, with one other important pancreatic disease which cannot be diagnosed by physical methods, and yet is capable of producing pressure on the duodenum, narrowing its calibre, and, as a result, inducing all the gastric phenomena that were present in this case. In chronic pancreatitis the head of the gland may partly embrace a portion of the duodenum and thereby cause almost complete stricture of the lumen of the bowel. I wish to emphasize the probability, then, that in the case under consideration the cause of the stomach dilatation was in the first instance pancreatitis. Had Cammidge's reaction been taken at this time I have little doubt it would have been positive. It was not, however, until the sudden onset of diabetes that the pancreas was suspected of being the seat of the mischief. The test was performed by an expert, with every precaution taken to prevent fallacy in making the test. It was positive, and corroborated surmises which before could not be definitely proved. Two other signs of chronic pancreatitis naturally presented themselves to my mind—a fatty character of the motions and jaundice. A chemical analysis of the faeces was not made for unsaponified neutral fat, but the appearance of the motions suggested excess of fat and fatty substances. Jaundice was never present, which was unusual, as the bile duct, as a rule, is pressed upon, and causes obstructive or catarrhal jaundice. The outstanding symptoms and signs were the dilatation of the stomach, the marked wasting, the character of the motions, the pancreatic reaction, and, lastly, diabetes.

Diabetes is an uncommon accompaniment of pancreatic disease, and when it does occur it indicates an extensive involvement of the parenchyma of the pancreas. Mr. Mayo Robson says that "the appearance of sugar in the urine, along with other signs of disease of the pancreas, points to a widespread and advanced lesion." The islands

of Langerhans, which are supposed to yield an internal secretion that is capable of exerting an influence over carbohydrate metabolism, become cut off, or their cells are replaced by connective tissue. An intercalary cirrhosis is set up, and Opie has shown that a hyaline metamorphosis is often strictly limited to the islands of Langerhans, while the glandular acini remain intact.

This case presented a somewhat interesting picture of a chronic inflammatory affection of the pancreas, giving rise in the first instance to gastric symptoms, relieved partly by gastro-enterostomy, and, in the second place, by alteration in the bulk of its substance, to diabetes mellitus. The etiological factor in the production of a primary interstitial pancreatitis is not yet known, but no doubt it bears some close relationship to cirrhosis occurring in other organs. The patient is rapidly losing flesh and strength, and although no grave complications of diabetes have as yet manifested themselves, little improvement can be expected either by medicinal or surgical measures.

In conclusion, let me add that I believe the operation of gastro-enterostomy in this case served one useful purpose—it prevented most likely the onset of "gastric tetany." All the elements conducive to gastric tetany were present—dilatation of the stomach with free hydrochloric acid, and prolonged dehydration of the tissues from the diabetes. As I have shown elsewhere, autointoxication and dehydration of the tissues play an important part in causing "gastric tetany," and in all these cases a gastro-enterostomy has diminished the mortality of the disease.

THE CAUSATION OF INGROWING TOENAIL, AND THE LOCATION OF GOUT.

BY G. ARBOUR STEPHENS, M.D. LOND.,

SWANSEA.

THE textbooks usually describe the cause of this inconvenient, uncomfortable, and painful condition as being tight and badly-fitting boots.

If tight boots are the cause, then all the ladies of the land should be sufferers, and chiropody should be a valuable branch of surgery. If badly-fitting boots are the cause, then all the children in cottage homes and most charitable institutions should be sufferers. With so universal a cause, ingrowing toenail ought to be much more prevalent than it is, and on both feet.

I venture to suggest that a more likely cause is the position of the foot during sleep. Most people sleep on their side, but were they asked how they placed their feet, very few could give a correct answer.

What usually happens is that a person on first taking up the side position, places his two feet side by side, but in a very short time the upper one slips down on to the bed, so as to lie wholly or partially on the bed alongside the other. If it slides but a short way, then it lies with its weight resting on the toes, and it is this constant pressure on the side of the big toe during hours of unconsciousness, that gives rise to the pathological condition.

Most persons at some period have experienced what is popularly known as the "fidgets" when getting into bed in an irritable and disturbed condition; they are restless, and do not know what to do with their feet, and at some stage they would notice, were they so disposed, that the upper foot was twisted round the lower one, with the big toe dug into the bed.

Most of the cases I have treated have suffered with the left foot, but in those persons who have had the right toenail affected I found the habit of sleeping on their left side. One patient I had with both nails ingrowing, but he was a ship's officer who had the habit of digging both feet against the side of his bunk.

The accompanying photographs may help to make the matter a little clearer.

Fig. 1 illustrates a position very commonly taken up by sleepers, and shows the pressure to which the big toe is subjected, sufficient to bend it out of the normal position. Fig. 2 shows the foot of a much older patient and the result of pressure exerted for many years.

One can understand from an examination of Fig. 1 the strain to which the joint at the ball of the big toe is

subjected, and in a person with an approaching attack of gout it is easy to understand why it is that a joint that has been under such continuous strain for about five hours

Fig. 1.

should be the spot selected at five o'clock in the morning for the exhibition of the most typical symptom.

One member of the profession, on hearing my suggestion as to the cause of ingrowing toenail, facetiously suggested

Fig. 2.

that we had better go to bed with our boots on; but, although we cannot all follow him in that habit, I venture to think that ingrowing toenail might be warded off, especially in children, by the wearing of a specially made toecap.

THE EFFECTIVE TREATMENT OF ACUTE AND SUBACUTE RHEUMATISM.*

By D. B. LEES, M.D., F.R.C.P.,

CONSULTING PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

[WITH SPECIAL PLATE.]

The title of this paper is intended to imply that the treatment of acute and subacute rheumatism, as advised in the textbooks and as usually carried out in practice, is inadequate and unsatisfactory. It is true that a great advance has been made since the days when it was maintained that cases of this disease did as well upon mint-water or upon lemon-juice as with any powerful drugs. In those days, as some of us can remember, there was no great exaggeration in the story of the physician who was asked "What is good for rheumatism?" and who replied, "Six weeks." At that time it was common for rheumatic patients to remain in hospital for weeks, and the very painful and persistent arthritis, with the profuse acid sweats, formed a clinical picture which is now not seen in hospital wards. Fatal hyperpyrexia, now extremely rare, was then not uncommon. There was, however, even then reason for thinking that treatment by alkalis was of some distinct advantage, in spite of the fact that the alkali employed was generally a salt of potash, and therefore not free from depressing effects, and that it was administered only in small quantities. An investigation of the clinical records of Guy's Hospital, which I made in 1874 as the basis of my thesis for the Cambridge M.D. degree, seemed to me to show clearly that the alkaline treatment certainly gave the best results. Yet these results left much to be desired, and the ineffectiveness of the treatment of acute rheumatism was one of the reproaches of medicine.

It is clearly seen by us all how great an improvement has been effected by the introduction of salicylate of soda. The rapid relief of pain, the fall of temperature, and the shortened duration of the illness are results which follow, we all agree, the administration of this drug. Yet the remedy, it must be confessed, has some side-effects which are annoying and which tend to limit its usefulness. Without much investigation whether these hindrances could be removed by some modification of the method of administration, physicians have been inclined to desert the simple salicylate in favour of some of the organic compounds of salicylic acid provided for us by the ingenuity of German chemists. But the most commonly used of these, acetyl-salicylic acid, the so-called "aspirin," cannot be combined with an alkali, hence we are at once deprived of a useful ally of sodium salicylate; and though free from some of the side-effects of salicylate, it may produce the most dangerous symptoms of salicylate poisoning, as proved by the case of the girl which I have elsewhere narrated who became comatose with typical "air hunger" after seven 15-grain doses of aspirin given in two and one-third days.

The use of sodium salicylate is also hindered by the superstition still prevalent among us that it is a depressant to the heart. The origin of this mischievous notion was probably due, in the first place, to impurities in the drug when a large demand suddenly arose through its early reputation as an antirheumatic. But the drug as now supplied to hospitals is of great purity, and careful observation of its effects for many years enables me to say deliberately that, when given to a rheumatic patient, it does not cause any weakening of the cardiac action. But it must be remembered that the rheumatic toxæmia itself always causes more or less cardiac weakening, and that this may sometimes become specially manifest. If at the time salicylate is being taken, the remedy is almost certain to be blamed for what is in reality one of the effects of the disease. It must be borne in mind, first, that a similar cardiac failure occurs in diphtheria and in influenza, quite apart from the action of any drug, and, secondly, that in every case of acute or subacute rheumatism the cardiac muscle suffers more or less. Endocarditis occurs only in a certain number of cases, and pericarditis is still less common, but the existence of a dilatation of the left ventricle can always be proved by careful percussion. Since I brought forward evidence of this fact before this society in 1898 I have never seen a case of acute or subacute rheumatism, in a child or in an adult, in which dilatation of the left ventricle did not exist. It appears to be invariably present in this disease. For a recent confirmation of this fact I may refer to the instructive article on rheumatic myocarditis contributed to the last number of the *Quarterly Journal of Medicine* (vol. ii, No. 5), by my friend and former house-physician, Dr. Carey Coombs, of Bristol.

The idea that sodium salicylate was a cardiac depressant, conjoined with the frequent difficulties in its administration, have caused physicians to give it only in small doses, and to discontinue its use as soon as or soon after the painful arthritis had subsided and the temperature fallen. It is a common experience that with this method relapses of rheumatic symptoms, in one form or another, have been frequent. It is also a common experience that often the temperature does not fall permanently to the normal, but that the evening temperature persistently rises to 99° or 100°, sometimes for a considerable period, especially in children; this should never be disregarded, for it means that the rheumatism is still active. It is therefore clear that the present treatment of rheumatism is inadequate, for though it controls it does not completely arrest the disease.

But it is not merely inadequate; it is also unsatisfactory, for it aims almost entirely at the cure of the painful arthritis, and pays little or no heed to the heart. It despairs of any real influence on the condition of this organ; it has no hope of diminishing a rheumatic endocarditis, and it usually ignores altogether the affection of the cardiac muscle. This is largely due to the fact that the earlier descriptions of acute rheumatism were the result of observations of the disease not in a children's hospital, but in hospitals for adults. Hence the present absurd arrangement of the textbooks, in which a description of its characteristics in adults is followed by an

* Read at the International Session of the Royal Society of Medicine, December 1st, 1908.

article describing what the writers are pleased to call its "peculiarities in childhood." Yet those who have worked simultaneously both in a hospital for children and in one for adults know well that it is in children that the disease is most frequent and most virulent; that in a considerable number of children the first attack is fatal, and that it fatally cripples the heart in a large number of the cases which survive. If every medical student of the past, and especially the gentlemen who now devote themselves to work in pathological laboratories and no longer visit the wards, had been compelled to study for three months in a children's hospital, we should have been spared such phrases as "rheumatism—that is, arthritis," and it would never have occurred to any one to describe as an "attenuated pyæmia" a malady which is as definite and distinctive, and as certainly microbial, as pneumonia or typhoid, which is one of the most virulent diseases of childhood, and which never produces pus.

We must give up the conception of acute rheumatism as a form of arthritis of adults, with occasional metastasis to the heart, and with certain "peculiarities" when it occurs in childhood. We must insist on the conception that it is a microbic toxæmia most virulent in early life, in which the heart is invariably affected to a greater or less degree, but the joints slightly and often not at all, with the peculiarity that when it occurs in adults the most prominent symptom is often a painful arthritis. It was from this point of view that I wrote the article on Acute and Subacute Rheumatism in the first volume of Dr. Allchin's *Manual of Medicine*, a few months before the epoch-making discovery of the rheumatic diplococcus by Poynton and Paine, and subsequent experience has only confirmed the conviction that this is the right way of presenting the facts.

If we are to seek for an improvement in the treatment of acute rheumatism, it must surely be based on the great and universally acknowledged curative effect of sodium salicylate in cases of rheumatic arthritis. This drug is not a cure for all kinds of arthritis; the remarkable results obtained by it in rheumatic arthritis are not observed if it be used for a tuberculous, pneumococcal, or gonorrhoeal joint inflammation. The prompt subsidence of a rheumatic arthritis under its use can only be due to a definite antagonism to the rheumatic process or microbe—in other words, its action is specific. The general unwillingness of physicians to admit this really unavoidable conclusion is due to the fact that the doses given are usually so small that only the more easily checked manifestations of acute rheumatism—the arthritis and the pyrexia—are fairly controlled. But if the inference is sound, may it not be possible, by a considerable increase of the dose, to produce a definite arrest of the disease in place of the imperfect control exerted by the small doses given at present? The question seems reasonable, but the possibility of an affirmative reply must depend upon the successful avoidance of the unpleasant symptoms which salicylate is apt to produce. Fortunately these are much less troublesome in children than in adults; indeed, among the toxic symptoms observed in adults vomiting is almost the only one which gives trouble in childhood.

The addition of sodium bicarbonate to each dose of the salicylate, in an amount always double of the amount of the salicylate, is a very effectual means of diminishing these side-effects, and the unpleasant taste may be covered by glycerine and peppermint-water or chloroform-water. The use of sodium bicarbonate in combination with the salicylate has two additional advantages. It helps to neutralize the acid toxins of the microbe, which Dr. Ainley Walker and Mr. Ryffel found, by special culture of the diplococcus, to be partly formic and partly acetic acids. And when we remember Dr. Gaskell's discovery, related in the third volume of the *Journal of Physiology*, that dilute lactic acid causes dilatation of the isolated frog's ventricle and finally arrest in diastole, while dilute sodium hydrate causes increased contraction with diminishing size until the ventricle stops in systole with its cavity reduced to nil, we may be reasonably sure that in man the administration of large doses of sodium bicarbonate must tend to cause a lessening of the pernicious cardiac dilatation of acute rheumatism.

Potassium salts should not be used, for the potassium base is really a cardiac depressant.

It is desirable to administer the combined salicylate and bicarbonate in frequent, but at first in moderate, doses. If the frequency be every two hours from 6 a.m. to 10 p.m., with one additional dose during the night, the total daily dose of each drug will be ten times the amount of the single dose. The amount of each should be increased daily, or every second day, until any unpleasant side-effect such as vomiting, deafness, tinnitus, vertigo, or a tendency to delirium is observed. In children, drowsiness, an acetone-odour of the breath, acetoneuria, and a slowing and deepening of the respiration must always be looked out for; if neglected, these may lead to "air-hunger" and fatal coma. Such symptoms are especially liable to occur if the child is costive, and may then be produced by quite small doses of salicylate, especially if the urine is too acid. They may be entirely prevented by careful relief of constipation, conjoined with the administration of a sufficient amount of sodium bicarbonate. Enough must be given to render the urine alkaline, and a surprising amount is often needed to effect this in a rheumatic child. Twice as much as the dose of salicylate is usually sufficient, but occasionally in young children it is not quite sufficient, and extra doses of the bicarbonate alone are necessary to make the urine alkaline. It is also a good rule, suggested by Dr. Reginald Miller, Medical Registrar at the Hospital for Sick Children, never to increase the dose of the salicylate unless the patient's bowels have acted on that particular day.

If, through neglect of these precautions, any of the above-mentioned symptoms of acid poisoning occur, it may be necessary to omit the salicylate altogether, and to increase the amount of the bicarbonate—even to a drachm hourly. With these precautions the administration of large doses of salicylate is quite safe. The only fatal case in my own experience occurred seven years ago, in a child to whom the salicylate was given without any bicarbonate and who was costive. The dose of salicylate was very small, only 20 grains daily (four 5-grain doses), but by an oversight it had been continued for ten weeks, and the importance of the prevention of constipation was not then recognized. The credit of first pointing out the danger of constipation in children taking salicylate belongs to Dr. Languead, formerly Medical Registrar at Great Ormond Street, who published a valuable paper in the *Lancet* for June 30th, 1906.

As soon as any unpleasant symptom due to salicylate occurs in an adult, or if vomiting occurs in a child, the administration of the drug should be suspended for a few hours. Two, or three, doses may be omitted; even a 12-hour interval may be allowed. But the elimination of salicylate in the urine is rapid, and the interval should not be long. After a few hours the medicine should again be given, but in reduced amount, one-half or two-thirds, according to the intensity of the symptoms observed. In many cases even the same dose as before will not produce a recurrence of the toxic effects, and I have sometimes suspected that they may be due in part to a bactericidal influence of the drug, destroying a large number of diplococci so quickly that their internal toxins are thrown in large amounts into the circulation. But it is wiser to reduce the dose of the remedy when it is again given, and to increase it the next day and continue to increase it as before. Almost always it is found possible in this way to reach a much larger dose than caused toxic symptoms at first, sometimes even three or four times as much. If in the course of this increase of dose any fresh toxic symptom occurs, the same plan of arrest and temporary reduction should be adopted as before. There are very few patients who cannot be trained in this way to tolerate large amounts of sodium salicylate, and there is really no need for any of the German substitutes. But one must expect to find every now and then a patient who is specially susceptible to this drug, as others are to mercury, quinine, iodide, or bromide, or even to articles of diet such as eggs.

The initial dose of sodium salicylate may be:

For an adult, 15 grains, or 150 grains daily.

For a child of 7 to 12 years, 10 grains, or 100 grains daily.

For a child younger than 7, 5 grains, or 50 grains daily.

Given in each case with twice the amount of sodium bicarbonate.

The daily increase of dose may with advantage be from 2 to 5 grains in the individual dose—that is, from 20 to

50 grains in the total amount given daily. The increase in the dose should be progressive until the evening temperature is and remains normal. The amount needed for a child may be nearly as great as for an adult, for in a child the infection is more virulent and renal elimination is more active. In some mild cases of acute and subacute rheumatism it may be sufficient to increase the dose of salicylate to 150 grains daily, but in many it is desirable to increase it to 200 or 250 grains, and in some severe cases to 350 or 400 grains. Chorea often requires 250 to 350, or even 400 grains. The doses usually given in this disease are much too small; large doses often cause rapid improvement. But in chorea time is often a necessary factor in the cure; damaged cortical cells require time for the restoration of their nutritive equilibrium after the arrest of the deleterious action of the rheumatic diplococci. A chorea treated early is often promptly arrested by large doses of sodium salicylate and bicarbonate, but a case which is already chronic will require a longer time.

In the chronic rheumatism of adults I have seen improvement commence when the daily dose reached 450 or even 500 grains, while small doses may produce no apparent effect.

The maximum dose in my own experience was given to a boy of 15 years, with severe pericarditis, endocarditis, a much dilated heart, and a tremendous crop of subcutaneous and subperiosteal nodules, many of large size. In this case the dose was raised without any difficulty, and quite rapidly, to a maximum of 600 grains of salicylate with 1,200 grains of bicarbonate daily. This dose was given for two days without any ill effect. After a day free from medicine, it was resumed at the lower rate of 500 grains of salicylate and 1,000 grains of bicarbonate, given for six days in each of the three following weeks. This was followed by a gradual reduction. An icebag was also applied over the heart for the cure of the pericarditis. The final result was most satisfactory.

What are the observed effects of these larger doses of sodium salicylate in acute and subacute rheumatism? Rapid relief of pain and subsidence of arthritis; fall of temperature to the normal with little or no tendency to subsequent rise; rarity of relapse; marked diminution of the torpidity and depressed look of the rheumatic child; and as regards the heart, an easily-observed reduction in size of the dilated left ventricle, while the cardiac impulse becomes stronger and more localized. It would be unreasonable to expect that a murmur due to endocarditis should immediately disappear, but the improvement in the condition of the muscular wall of the heart is often most striking. The rheumatic nodule is specially resistant to treatment, for its abundance of fibrous tissue tends to hinder a bactericide from reaching the diplococci which it contains. Yet under the influence of large doses of salicylate and bicarbonate even large nodules, such as were at one time said to be "equivalent to a sentence of death," will melt away. In the boy already mentioned as many as 216 nodules, some of large size, were counted on one day; yet when he left the hospital not a vestige of them remained. Examples of such nodules will be found in the special plate.

Is it possible to assist the curative influence on the heart by the use of any other therapeutical measure? The answer to this question is very decidedly in the affirmative. In rheumatic pericarditis the extraordinary value of the local application of ice is one of the most certain facts in therapeutics. I advocated the use of the icebag in pericarditis at the Nottingham meeting of the British Medical Association in 1892, and I have used it for the treatment of this condition ever since. Its curative influence is very great. But in using it two points must always be borne in mind. The patient's lower extremities must be kept constantly warm by hot-water bottles, and any considerable dilatation of the right auricle must be relieved by leeches before the ice is applied—the indications for leeches being

an extension of the cardiac dullness in the fourth right intercostal space to two fingerbreadths, rapid respiration, restlessness, and some degree of cyanosis of the lips and face.

The beneficial action of the icebag in pericarditis is clearly a local one, and it suggests the probability that this measure may be useful also in rheumatic myocarditis and possibly even in endocarditis. I think there is no doubt that the application of an icebag to a dilated rheumatic heart (with the precautions already mentioned) certainly causes a more rapid reduction in size of the left ventricle and an increase in strength of the cardiac impulse. And in some cases in which evidence of endocarditis has been present, I have observed under its influence a notable retrogression of the auscultatory signs. The earliest indication of an endocarditis is usually a systolic apex murmur, to which a doubling of the second sound at the apex is often soon added, and in some cases the second element of this double second sound becomes changed into a short mid-diastolic murmur. Under the local influence of ice I have noticed first the disappearance of the mid-diastolic murmur, and the reappearance of the double second sound, soon followed by the disappearance of the doubling, leaving only a systolic murmur and a second sound, and at a later stage the systolic murmur has tended to disappear.

I have gradually made more frequent use of ice in the treatment of cardiac rheumatism apart from pericarditis, and can recommend it as certainly helpful. But the two precautions already mentioned must be always remembered. The combination of ice to the heart with the use of large doses of sodium salicylate and bicarbonate has yielded very remarkable results in practice, and I speak from the

experience of careful trials carried on for three or four years in a hospital service of 60 beds, consisting of 25 beds at the Hospital for Sick Children, with 5 beds for children and 30 for adults at St. Mary's Hospital.

My conviction is that if these methods were adopted universally, the lives of many rheumatic children would be saved, and that an enormous reduction would be effected

in the prevalence of rheumatic heart disease in the adults of the next generation. How much suffering would thereby be prevented can be readily imagined by those who have watched the miserable downward progress of cases of chronic heart disease, the result of former rheumatism.

I commend this method of treatment to your favourable consideration. I submit no statistics, for statistics presented by the advocate of some special treatment are justly suspected as tainted by an involuntary bias. But I ask you to try the method for yourselves. And if to some there seems to be danger in these large doses, I would beg you to remember that an excessive timidity in dosage, due to the fear of doing harm, may often be more detrimental to the patient than a cautious boldness. In medicine a sin of omission is more lightly regarded than a sin of commission, but it may be even more disastrous. In advocating a bolder course I have endeavoured to state clearly the precautions which are necessary. Let no one adopt the former and yet neglect the latter.

A COLLECTIVE investigation on cancer within the boundaries of the State of Hamburg has been made. The material gathered will be edited by Dr. Koerber.

AN Italian Committee for the Study of Cancer has recently been founded. It is under the patronage of the King of Italy, and its Honorary President is the Sindaco of Milan, where are the head quarters of the committee. It is constituted on the same lines as the International Cancer Research Association founded at Berlin in 1908, and its objects are to encourage research on cancer and the publication of the results; to collect statistics on a uniform method; and to promote the establishment of institutes for investigation of cancer.

DESCRIPTION OF PLATE.

Fig. 1 shows many nodules around the elbows, and four or five subperiosteal nodules along the ulna.

Fig. 2 shows large nodules on the occiput, the scapular ridges, and the vertebral spinal processes.

Fig. 3 represents very accurately the many small nodules on the flexor tendons at the wrist in the same patient, but this photograph was taken some years ago from a patient under the care of Dr. J. A. Coutts, and is published with his permission.

REPORT CIX.

ON THE PRIMITIVE MUSCLE TISSUE OF THE HUMAN HEART.*

By ALEXANDER GIBSON, D.M., M.R.C.P.,

FROM THE DEPARTMENT OF PATHOLOGY, UNIVERSITY OF OXFORD.

[WITH SPECIAL PLATE.]

THE attention recently given to the more accurate analysis of the events taking place in the cardiac cycle of man has resulted in limiting the origin of the beat to certain regions. In the frog's heart we know that the beat originates in the sinus venosus, and it has been tentatively assumed that in mammalian hearts the beat originates in that part which represents the sinus venosus of the amphibian. Recent clinical work, as for instance that of G. A. Gibson and of K. F. Wenckebach, has directed attention chiefly to the superior vena cava as the probable site in man. In the search

for a special muscular tissue originating the cardiac beat three important anatomical contributions to our knowledge have recently been made. Tawara,¹ in his investigations on the auricular connexions of His's bundle, is led to the conclusion that the region anterior to the orifice of the coronary sinus is the spot from which the fibres of this bundle originate, and he therefore infers that this region gives rise to the beat of the heart. Wenckebach² describes certain muscular bundles in the wall of the superior vena cava of a paler colour than those of the auricular muscle. They are seen as ring-like bundles surrounding the proximal part of the vein; single bundles stretch upwards away from the auricle. He describes a marked separation by connective tissue and fat of the musculature of the superior vena cava from that of the auricle when viewed from without. Muscle bands stretch from the superior vena cava to other parts of the heart, especially to the right auricle; these bands can be seen on dissecting the posterior aspect of the heart, and are especially marked in hypertrophic conditions that affect the auricles.

Keith and Flack³ have described a type of muscular tissue in the hearts of several species of animals, including man, which they suppose to be that in which the normal stimulus for the contraction of the heart arises. In the region of the orifice of the superior vena cava associated with a vessel which partially encircles the vein they have described a type of muscular tissue differing markedly from the ordinary muscular tissue of the auricle in being closely embedded in connective tissue, the fibres being fusiform with elongated nuclei and the fibres themselves having a plexiform arrangement. This tissue they describe as similar in its structure to that occurring at Tawara's node in the lower part of the interauricular septum.

OBJECTS AND SCOPE OF THE PRESENT RESEARCH.

This research was undertaken with the view of ascertaining by macroscopic and microscopic examina-

* Towards the expenses of this research a grant was made by the British Medical Association on the recommendation of the Science Committee of the Association.

tion of the human heart what differences, if any, existed in the arrangement and type of muscle fibre in the regions in which most of the primitive and undifferentiated tissue was likely to exist, and from the results of this work to attempt to formulate some working hypothesis that would enable us to associate certain functions with definite anatomical parts of the cardiac musculature. The material used has been from the *post-mortem* room, but in all cases the hearts have been taken from young adults who had died from accident or disease not associated with the cardio-vascular system. The hearts were allowed to soak in running tap-water for twenty-four hours; then, having been stuffed with cotton-wool, they were placed in Kaiserling's formalin solution, afterwards in 90 per cent. alcohol, and finally, for preservation, in Kaiserling's glycerine solution. The portions cut out for microscopic examination having been washed well in running tap-water to remove all glycerine, were embedded in paraffin in the usual way. The stains used throughout for the ordinary examination of sections have been hematoxylin and Van Gieson's picric acid fuchsin; for special purposes Weigert's resorcin fuchsin and Cresylleucht violet have been used.

THE NAKED-EYE FEATURES OF THE AURICULAR ENDOCARDIUM.

If a normal heart be opened and the right auricle

examined from the inside, the endocardium will be seen to present certain thickenings arranged slightly differently in different specimens, and in very different degrees, but preserving some uniformity. Fig. 1 is intended to display these points; the region of the superior vena cava has a whitish endocardium, that near the orifice of the inferior vena cava is yellowish, towards the auriculo-ventricular ring the muscle becomes more visible owing to the endocardium becoming transparent. In the figure the portions where the muscle can easily be seen through the endocardium are dotted. It will be observed that the edge of this thickened

endocardium in relation with the superior vena cava is sharp, except at one point where in the heart figured there is a free cord of thickened endocardium coming downwards to meet and join a tongue of thickened endocardium stretching anteriorly from the region of the foramen ovale. Where the auricular wall becomes trabeculated owing to the formation of the auricular appendix the thickened endocardium is well seen on the convexity of the trabeculae gradually fading away as they stretch towards the more dilated parts of the appendix. The pattern here described is by no means uniform in all hearts, but in young persons some such pattern can usually be found. In older persons the endocardium is most often uniformly covered with a whitish layer, but the parts which show the greatest thickening in the young adult are as a rule also thicker in the old person. The endocardium of the left auricle is for the most part uniform, and of a yellowish-grey tint; in no places in normal hearts is it usual to see the reddish-brown of the muscular fibres through the endocardium except in the auricular appendix.

This thickened endocardium has been examined histologically in a number of regions, and has been found to consist largely of fibrous tissue staining red by Van Gieson's stain. In its substance, or immediately in relation with it, are large numbers of muscular fibres, occurring singly or in bundles, mostly of the smooth or unstriated type (Plate, Fig. a). In the greater number of sections examined this is the only type seen, but in others the type is different, and may be traced through a very

definite series of changes which it will be well to describe before going further into their distribution.

DESCRIPTION OF THE DIFFERENT TYPES OF FIBRES.

In the plate will be seen drawings of certain types of fibres met with in the sections examined. These must be taken as specimens of their classes, for amongst them very few are exactly alike. Fig. *a* is a drawing of the whole of one and part of another smooth muscular fibre as met with commonly in the endocardium. Figs. *b* and *c* are smooth fibres, but slightly shorter and thicker than the normal type. Fig. *d* is still thicker, and shows on either side near the nucleus two longitudinal bands which by careful focussing can be seen to be cross-striated; this is seen also near one pole of the cell. Fig. *e* shows a fibre markedly thickened at one end directly continuous with a long tail-like process

indistinguishable from a smooth muscle fibre. Fig. *f* has a similar but shorter tail-like process, attached to which is a smooth muscle fibre; the cell contains two nuclei, and shows only the faintest evidence in one spot of cross-striation. Fig. *g* is a similar but much broader cell, with only the faintest evidence of striation. Fig. *h* shows a large irregular muscle syncytium in which only at one point could any cross-striation be detected. Fig. *i* shows a nearly normal auricular muscle fibre with a non-striated process side by side with a fibre which for the greater part of its length shows no striation. Fig. *j* is a fairly common type, and seems to be a bundle of non-striated fibres becoming thicker, the next stage being seen in Fig. *m*, which is a muscle syncytium showing irregular cavities containing nuclei; the substance of the fibre appears to be an interlacement of fibrils, stretching for the most part longitudinally. The fibre here depicted, though non-striated in the section from which the figure was drawn, showed some striation in a neighbouring section. This type is very nearly allied to one figured by Tawara (Table V, Fig. 1). Fig. *o* is another syncytium which is very similar in appearance to Fig. *m*, except that it is striated and the bundles which compose it are more longitudinally arranged. Fig. *k* is a fibre met with occasionally in association with the fibres depicted in Figs. *c* to *j*. Fig. *n* is an extremely common fibre, and is of the type of certain Purkinje fibres; for the most part it is striated, though, as shown, many portions have no striation. Fig. *p* shows a reticular type of fibre and its junction towards more normal auricular muscle fibre.

These fibres may be roughly classified into three groups: first, those more nearly related to smooth muscle tissue (Figs. *b*, *c*, *d*, *e*, *f*, *h*, and *i*); secondly, those having a syncytial arrangement (Figs. *l*, *m*, *n*, *o*); and thirdly, those of a reticular structure (Figs. *g* and *p*).

THEIR DISTRIBUTION.

It is too early as yet to do more than indicate the positions in which some of these fibres may be found, but there

are certain regions in which more of one type may be found than the other. It may be said at once that no mere cursory examination would be sufficient to discover even a few types, not only numbers of sites have to be examined, but numbers of sections in various parts. Speaking generally, the greater number of the first type, those which can be traced from smooth muscle tissue, are to be found in the region of the foramen ovale and in the valve of Vieussens.

The fibres of the second class are found most frequently in relation to the superior vena cava and the parts immediately related thereto. Fig. *m* was drawn from a section including part of the superior vena cava and the auricle; Fig. *n* was found in the valve of Vieussens, but is a very common type in the superior vena cava; Fig. *o* was found immediately under the endocardium of a trabecula of the right auricular

appendix, where many other such fibres can be found.

The third class, the reticular fibres, constitute the tissue described by Keith and Flack as the sino-auricular node, found in relation to the vessel which encircles the greater part of the circumference of the superior vena cava. Fig. *k*, however, was found in the valve of Vieussens. All the types of muscle fibres mentioned lie either embedded in the fibrous tissue of the endocardium or very closely in relation with it.

THEIR SIGNIFICANCE.

The presence of the forms mentioned in the first class is probably to be explained from the consideration of the heart as a tube originally developed from elongated cells which showed no striation, the striation only gradually developing it when the organ became rhythmically contractile; those parts which show such fibres in the adult being the remains of the unfinished part of the cardiac musculature, that zone between the highly differentiated tissue of the auricles and the undifferentiated muscular tissue of the veins. Certain neoplasms, too, in the heart and elsewhere show a similar series of changes.

The syncytial fibres may have some function originating the beat of the heart; this would be borne out by their being found largely in the neighbourhood of the superior vena cava, where experiment suggests that the beat usually starts, and their presence in other parts would also be confirmed by the experiments of Erlanger and Blackman,⁴ who find that the beat may arise in a large number of different places in the auricle. These speculations are suggested by the type, arrangement, and site of fibres, and must not be taken as anything more than hypotheses for future work which is being undertaken.

REPORT CX.

ON THE DIFFERENCE IN CONTENT OF
IMMUNE SUBSTANCES IN BLOOD
SERUM AND PLASMA.*

BY

GEORGES DREYER, and E. W. AINLEY WALKER,
M.D., M.D.,
PROFESSOR OF PATHOLOGY, LECTURER IN PATHOLOGY,
IN THE UNIVERSITY OF OXFORD.

[Abstract.]

SERUM and plasma obtained from rabbit's blood have been compared as regards their agglutinating action on the *Bacterium coli* before, during, and after immunization with that organism.

It is found as a general proposition that the plasma of an animal is more strongly agglutinative than its serum, owing, as we believe, to the loss of some of the agglutinin of the latter in consequence of an "absorption" of agglutinin by the constituents of the clot formed in the blood from which the serum is derived.

This general proposition being fully established by the observations made, it follows that if the serum is at any period found to be as strong as the plasma, and still more if it is found to be the stronger of the two, its increase in agglutinating power must be due to some factor partially or completely absent from the plasma, which adds enough agglutinin to balance, or more than balance, as the case may be, the loss by "absorption."

In the observations now recorded the serum has been found always to be stronger than the plasma during the period of latency and rise in the immunity curve of agglutinin production. And the percentage difference between the two is shown to be greatest during the earlier portion of this period, that is, at a time which corresponds to the time of maximum leucocytosis following the inoculation.

It is, therefore, suggested that the factor in question causing increase in the agglutinins of the serum is the leucocytes of the blood, which are allowed to break up in the sample used for the preparation of serum, but are rapidly separated from the plasma in an extremely powerful centrifuge.

When there is no longer leucocytosis in the blood, and the activity of agglutinin production in the body begins to wane, the amount of agglutinin derived from the leucocytes present no longer overpowers or even equals the loss by "absorption"; and from this point onwards the plasma always shows the higher values.

These observed facts explain the disagreement in the results obtained by previous workers, who paid no regard to the particular stage of immunity with which they were dealing when they made their comparisons between the serum and plasma.

The view here put forward is strengthened by the observation, several times repeated, that if in an immunized animal a new increase in agglutinin production be induced by the inoculation of a totally different micro-organism, this non-specific stimulation rapidly results in the serum again becoming stronger than the plasma in specific agglutinating power. We are unable to offer any explanation of this result unless it be dependent on the increase in the activity and number of the leucocytes present in the blood.

But if this explanation be the correct one, it affords strong evidence that the leucocytes and leucocytic tissues (bone marrow, endothelia, etc.), some, or all of them, are concerned in the development of immunity, and are the source, or, at any rate, a source, of origin of the specific antibodies—agglutinins.

Incidental evidence has also been obtained which shows that plasma, as contrasted with serum, is relatively destitute of complement. And this affords additional support to the view that the complement of blood is derived from its leucocytes.

REPORT CXI.

OBSERVATIONS ON THE PRODUCTION OF
IMMUNE SUBSTANCES.*

BY

GEORGES DREYER, and E. W. AINLEY WALKER,
M.D., M.D.,
PROFESSOR OF PATHOLOGY, LECTURER IN PATHOLOGY,
IN THE UNIVERSITY OF OXFORD.

[Abstract.]

If an animal (rabbit) which has been immunized against the *Bacterium coli*, and whose immunity has passed its maximum by a longer or shorter interval of time, receive an inoculation of a different organism, a new rise occurs in the curve of specific *coli* agglutinins in its blood serum. But if the interval which has elapsed before this inoculation is made be of such a length that the immunity of the animal has ceased to be measurably greater than it was before immunization was originally begun, no perceptible increase in agglutinins occurs.

That is to say, that the cells and tissues which are thrown into activity by the new inoculation are precisely those which were already occupied in the formation of agglutinin, and whose stimulation, therefore, leads to its increased production.

Now the tissues which are known always to be stimulated by bacterial inoculations are the leucocytic tissues of the body (bone marrow, lymphatic glands, endothelia, etc.). The observations recorded, therefore, tend to show that these tissues are the site, or a site, of production for the specific antibodies—agglutinins.

The question whether possibly other tissues also are concerned in the production is not here considered. At present we are not aware of any clear and satisfactory evidence in its favour.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

INDUSTRIAL SYPHILIS.

THE notes of a case of syphilis published by Mr. Snell in the JOURNAL of December 5th, 1908, are of paramount importance, and afford another piece of evidence for the compulsory notification of syphilis as an infectious disease. It reminded me of a similar case I had early in that year.

A young woman, aged 22, engaged as a coatmaker, consulted me for a sore she had had on her lip for some week or ten days; it was increasing in size. On the first visit I did not suspect anything of a specific nature, thinking it was simply an infected herpetic vesicle; and also I knew her and her family to be most virtuous. But at her next visit the appearance of the sore raised my suspicions, and upon examination I came to the conclusion that it could be nothing else but a primary chancre. This was afterwards confirmed by a consultant, and the train of symptoms which followed, but they were of a mild character. When I made up my mind as to the correct diagnosis, I endeavoured to find out how she became infected. I put the question as guardedly as possible, but could not elicit anything definite. I told her I should like to see her mother, when, as delicately as possible, I put the case before her, asking particulars about her companions and her work. Her companions at home were above suspicion, but at her place of business it was different; she was engaged in her occupation in a workroom where there were several women engaged, and each one had a different part of the coat to make, and in its various stages was passed from one to another; the girl herself suggested that the sore might have been produced by dye in the cloth with which she was working. To get the hem of the cloth into a workable condition she was in the habit of pressing it against her chin and passing it across several times, so as to make it flat and even. I then inquired as to the health of her fellow workpeople, and the majority

were very respectable, getting good wages at hand-made work. She told me that the one from whom she received the garment had not been well for some time, and had sores in her mouth and other such symptoms that made it certain as to the source from whence she had become infected. This was corroborated by her mother, who made inquiries; though she never suspected the disease. I impressed upon her the gravity and the length of time for treatment.

I maintain, in the interests of the community at large, that syphilis should be made notifiable—as we see here how the innocent suffered—anyway in industrial centres.

GRAY VALLEY COTTAGE HOSPITAL.

ABDOMINAL LACERATION: EXTRUSION OF VISCERA: OPERATION: RECOVERY.

(Reported by T. W. BAILEY, Honorary Surgeon.)

The patient in the following case was admitted under my care in the afternoon of July 31st, 1908, with the following history: The same day, after a dinner of bread, meat, and beer, and a large Spanish onion, he had been riding a bicycle. He was wearing old-fashioned front-flap trousers, and in the left-side pocket of these was carrying a quart bottle containing tea. The bottle got in his way several times, and finally jammed between his body and the handle bars, throwing him on to his right side. On picking himself up, he found the bottle sticking into his stomach, through the band of his trousers, and broken at the shoulder. On withdrawing it gut followed. He was conscious of no pain from first to last, but collapsed on trying to get to the door of a house close by. This was the house of my partner, Dr. Curtis, who, finding him almost immediately afterwards, packed the protruded viscera with warm boracic lint, and brought him in a cab to the hospital, a distance of some two and a half miles.

State on Admission.—On arrival he was much collapsed, and the abdominal parietes were found torn through almost transversely, the right extremity of the tear being about an inch above and to the left of the umbilicus. Filling and extruding from the wound was a mass of viscera the size of a cottage loaf, consisting of part of the stomach, the transverse colon, and some omentum. In the stomach was a 2-inch wound through which food was exuding in considerable quantity.

Treatment.—Operating with the help of Drs. Curtis and Bennion, and the patient being under ether. I attended to all bleeding points first. There had been considerable hæmorrhage both from the torn parietes and the stomach. The latter was then washed out through the wound in its anterior wall, and the opening closed by continuous suture. The peritoneal cavity was then thoroughly irrigated. The next step was to cleanse and pack back all intestine, which necessitated some enlargement of the wound in order that the peritoneum, more freely torn than the muscles, might be properly sutured. The external wound was then closed with three tiers of stitches, room being left for a drainage tube of large calibre.

Progress and Result.—For the first twenty-four hours the man remained greatly collapsed, but after that he improved, and so rapidly that the drainage tube was left out in a few days. The wound, in short, healed by first intention, and the man had an uninterrupted recovery.

REMARKS.—My reason for reporting this case is, of course, the severe nature of the injury and the fact that a considerable time must have elapsed during which the man had a considerable quantity of his abdominal contents outside his abdomen more or less exposed. The happy issue of the case was no doubt in a measure due to the protruded mass of intestine effectually plugging the abdominal wound, and thereby preventing the escape of the stomach contents into the general peritoneal cavity.

THE thirty-sixth meeting of the Bæneological Congress will be held at Berlin under the presidency of Professor Brieger from March 4th to 8th.

CHARTERS J. SYMONDS, M.S., F.R.C.S., in the Chair.

Mediastinal Growths.

DR. R. CECIL B. WALL, in the course of a paper on mediastinal growths, said that sarcoma of the mediastinum was a disease chiefly of the middle period of life. It was generally associated with pulmonary symptoms, of which cough and dyspnoea were the chief and hæmoptysis not uncommon. Symptoms due to the bulk of the growth were often present, such as stridor, dysphagia, and oedema from venous obstruction. Pain which could be ascribed to metastatic deposits was seldom a prominent symptom. The signs usually indicated either a pleural effusion, which was not uncommonly brown from altered blood pigment, or the presence of a solid mass in the mediastinum or lung. Evidence of impairment of function of various structures of the mediastinum was frequently found. Cancer of the mediastinum occurred somewhat later in life. Pulmonary symptoms were less commonly prominent, and metastatic deposits in bones or implicating nerves usually brought the patient under the notice of the physician. Signs of pulmonary or mediastinal disease were often absent; if present, they tended to indicate obstruction of a bronchus or effusion resulting from pleural metastases rather than massive deposits in the lung or mediastina. In Hodgkin's disease and acute lymphatic leukaemia the presence of a mass of lymphatic gland tissue in the thoracic cavity was merely accidental, but when present might produce symptoms and signs owing to its bulk. Cancer of the pleura seemed to be a disease of later life tending to produce symptoms, as in the case of mediastinal cancer, from metastatic deposits and signs of pleural effusion.

Lymphocythæmia.

DR. LEONARD GUTHRIE and DR. W. D'ESTE EMERY, in a paper on a case of lymphocythæmia in a boy aged 6 years, said that although lymphocythæmia so-called was undoubtedly a definite and separate disease as shown by the *post-mortem* appearances, it was doubtful whether it could be diagnosed with certainty by examination of the blood during life. Excess of lymphocytes was held to be pathognomonic of the disease, but it must be remembered that in early childhood lymphocytosis might be present in many other morbid conditions of the blood, all of which were protean in character so far as the results of examination of the blood were concerned. With regard to terminology, it seemed paradoxical to describe the case brought forward as one of lymphocythæmia when the total leucocyte count only amounted to 2,000 per c.mm., yet though not in excess in the blood, the lymphocytes, if indeed they were lymphocytes, were deposited in incalculable numbers in the tissues and organs.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

At a meeting on December 10th, 1908, Dr. HERBERT STENGER, President, in the chair, Dr. ARNOLD W. LEE and Dr. E. J. SIDEBOTHAM read a paper on the *Bacteria of the puerperal uterus*. They had made observations on a series of fifty-eight patients in whom the puerperium was normal. The results of these experiments appeared to show (1) that the uterine secretion after delivery contained organisms in the great proportion of cases after the second day; (2) these organisms closely resembled those found in puerperal infection; (3) streptococci were present in a considerable number of cases, and often showed marked hæmolysis; the discovery of hæmolytic streptococci in the lochial discharge was no certain indication of the existence of infection. Dr. DRUMMOND ROBINSON thought that the weak spot in the paper had been indicated by the authors themselves. It was undisputed that the cervix always contained micro-organisms, and it appeared to him that it would always be impossible to obtain material from the cavity of the uterus without contaminating such material with micro-organisms from the cervix. Mr. ALBAN DORAN read notes of a case in which a woman, aged 35, subject to irregular menstruation for three years,

was seized on April 19th with acute hypogastric pain. A swelling developed in the left iliac fossa. When the patient was admitted into hospital on July 3rd the mass was found to be an oval, well-circumscribed cyst; there was no milk in the breasts, and there had been no show of blood of any kind for several months. At operation on July 10th he discovered a *posterior tubo-ligamentary pregnancy*, opened the sac, and extracted a live fetus; the greater part of the placenta came away with it. The cavity of the cyst was firmly packed with gauze, and a purse-string suture passed round the cut edge of the cyst wall to check hæmorrhage, but not drawn tightly, as the large intestine ran along the back of the cyst. The cut edge of the cyst was sutured to the parietal peritoneum. There were two fresh attacks of hæmorrhage checked by pressure, and forty-eight hours after the operation the packing was removed. There was much fetid discharge for several weeks, but the hæmorrhage never recurred. During the last week in November menstruation returned. The speaker considered that, as there was always great risk of hæmorrhage after operations performed late in ectopic pregnancy, the method which he had adopted was good surgery. Mr. HERBERT PATERSON communicated a case of *Extrauterine gestation* in which operation was performed during the sixth month of pregnancy. The patient was a woman, aged 29, who had suffered from abdominal pain for one month before her admission into the London Temperance Hospital in March, 1908. In the right iliac region and extending to the level of the umbilicus was a smooth, rounded, fixed, tender swelling. The catamenia had been perfectly regular up to the time of admission. A few days after admission the patient became markedly jaundiced, but this lasted only for two or three days. The fetus measured just over 6½ in., and weighed 8½ oz., and the fetal circulation was active at the time of operation. For forty-eight hours the patient was extremely ill, vomiting frequently on account of intestinal paresis. This was treated with repeated doses of calomel, and as soon as the bowels were opened the vomiting ceased and the patient rapidly recovered. He considered the important points in the treatment of such cases to be: (1) The avoidance of the use of ligatures inside the sac, which, as they were certain to become infected, greatly delayed convalescence; (2) the arrest of hæmorrhage by gauze packing; (3) the treatment of the intestinal paresis caused by the gauze packing by early and repeated doses of calomel; (4) the withholding of morphia; (5) the use of continuous saline injection by the rectum, after the method introduced by Dr. J. B. Murphy. The President (Dr. Herbert Spencer) thought that the cases were of much value, since cases of extrauterine pregnancy with living children in the second half of pregnancy were rare. Of three such cases which he had seen, only the last recovered. In the first he left the placenta behind, in accordance with the teaching of the time; in the second he removed the placenta and membranes, and packed with gauze, but the patient died the same night of syncope. In the third he treated the case in the same way as the second, and recovery resulted. Mr. Paterson estimated the pregnancy in his case as "in the sixth month," the fetus only measuring 6½ in. The size usually given for an intra-uterine fetus of 5 calendar months old was 10 in., and for one of 6 calendar months old 12 in. He did not know of any tables giving the size of the ectopic pregnancy fetus, but it was important that the age of the pregnancy should be correctly stated, as the mortality was enormously increased in the second half of pregnancy.

CLINICAL SECTION.

At a meeting on January 8th, Sir T. BARLOW, President, in the chair, Dr. JAMES MACKENZIE demonstrated the *Clinical polygraph*, an instrument which he had invented to replace the bulky revolving drum covered with smoked paper, formerly in use to record various vascular movements. Taking the time of the radial pulse as the standard he was able by a simple instrument to locate the times of other cardio-vascular movements. A small cup received the impressions of the pulsations, and a tube transmitted the impressions to a tambour and lever, the tambour being attached to a Dudgeon and Jacquet sphygmograph. This cup, or receiver, was a circular small shallow metal vessel, and, in use, its open mouth was applied over the pulsating part, so closely that

its edges excluded all communication with the outer air. From its roof arose a narrow pipe, ½ in. long, to which was fitted an india-rubber tube 3 or 4 ft. long, connected by its other end with the tambour, which (the tambour) supported a writing lever 6 in. long, and was attached to the upright stem of the sphygmograph. With this instrument he had made many observations and learnt much, but had also found need for a continuous tracing. This had led to the invention of the *ink polygraph*, whereby ink tracings of indefinite length could be taken on a gradually unwinding roll of paper controlled by clockwork. There were thus two tambours with levers, one to record the radial pulse, the other the movement under observation, and a time marker moved by clockwork. Dr. Mackenzie next showed many records which he had taken by the polygraph, and described the methods by which they should be read and the inferences to be drawn therefrom. Amongst other important observations, he had frequently found a prolongation of the interval between the auricular and ventricular waves in the jugular tracing in cases of advanced mitral stenosis; this he ascribed to alteration in the excitability of the auriculo-ventricular band, and he had designated the rhythm *nodal* rhythm. This also explained the irregularity that occurred in cardio-sclerosis. Drs. Mackenzie and Lewis then demonstrated the method of using the instrument on the human subject. Dr. PAUL CHAPMAN (Hereford) said he had previously doubted whether the times of the various impulses could be definitely measured by Dr. Mackenzie's instrument. He himself had used an instrument by which pulsation was adapted to cardiac (not a radial pulse) record, but it required much skill to obtain thereby records of any value. He had now no doubt that the sequence of events was as Dr. Mackenzie had described, and thought the instrument shown was of great value in correlating cardiac and vascular records with the signs found by other means of clinical investigation. Sir LAUDER BRUNTON said the subject was full of difficulties. He much admired Dr. Mackenzie's skill and patience in obtaining these records, and his ability in deciphering them. He thought the polygraph would help much in the diagnosis and application of medicines to cardiac disease. He considered this the most convenient of recording instruments, though less expensive than many he already possessed. Sir JOHN BROADBENT thought that delay in ventricular contraction in cases of mitral stenosis might be explained in another way than that given by Dr. Mackenzie. As the orifice grew narrower, the passage of the blood through it naturally took a longer time, so that the delay could be explained on a purely physical basis. He also questioned the use of the term "nodal rhythm." In many cases of old-standing rheumatic heart disease, and in the hearts of old people, there was often much general fibrosis, so that it would be difficult to differentiate the auriculo-ventricular bundle. Dr. HERRINGHAM paid a high tribute to Dr. Mackenzie for the work which had led to his putting forward this new method of investigation, though he did not accept without question all that Dr. Mackenzie had said. Dr. THOMAS LEWIS said that the prolongation of the interval between the auricular and ventricular systole could not be explained mechanically. During the taking of a record this change would often occur quite suddenly. For twelve months he had used the method under discussion, and thought that examination of irregularly-acting hearts was futile without it. Dr. MACKENZIE, in reply, said that at this stage it was no longer always necessary to take a tracing. His explanation of the irregular rhythm, which he had called "nodal rhythm," was purely hypothetical, although he had given many reasons for it.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At a meeting on December 11th, 1908, Dr. WALKER DOWNE, President, in the chair, Dr. JOHN M. COWAN read notes of two cases of *Diaphragmatic palsy*. One of the patients suffered from peripheral neuritis of alcoholic origin, and the diaphragm was completely paralysed for three months. Thoracic respiration was good, and the ultimate recovery was almost complete. The second patient suffered from Landry's paralysis. Symptoms had commenced fourteen days prior to admission. She was found to be unable to move her limbs in bed or to lift her head; her diaphragm

was inactive, and she suffered from right third, fifth, sixth, seventh palsy more or less complete. The sphincters were active and sensation was normal. Improvement was manifest three days after admission, and on the eleventh day all movements were possible though they were weak. There was no atrophy of muscles, and the reflexes rapidly reappeared, and became even excessive. Recovery was good and complete. Dr. GEORGE M. GRAY demonstrated a dissected specimen of a limb showing congenital absence of the fibula. In its place was a firm fibrous band, to which, in addition to the usual muscles, was attached the popliteus. He also read notes of a case in which there was hernia of a loop of bowel through a foramen in an appendix epiploica. Dr. McLENNAN showed a boy, aged 13, who had been operated upon for a hydrocele of the tunica vaginalis and an encysted hydrocele of the cord. At the operation the encysted part of the hydrocele was found to communicate with a patent processus vaginalis. A radical cure for hernia was performed after removal of the hydroceles. The interest lay in the specimen removed. Had a hernia descended the patent sac it would have passed down behind the hydrocele of the tunica vaginalis, and would have formed a typical infantile hernia. Such a case as this was considered to go far in proving the sacular theory of hernia. The other points in favour of this theory were referred to as the *post-mortem* finding of patent peritoneal processes without the presence of herniae or the history of such. It was noted also that ascites, which did not produce a hernia by forming a sac, often revealed its presence by entering a patent processus vaginalis showing as a congenital hydrocele. Such late congenital hydroceles often indicated a subscutaneous peritonitis. The only similar effect of ascites was occasionally to protrude the umbilicus. Further, intra-abdominal tumours occasionally grew down such processes and formed the contents of herniae, yet no one would imagine that such growths had the power to force the formation of hernial sacs. The descent of the testicle requires a large opening, hence the prevalence of herniae in male infants. In the female similar herniae (oblique inguinal) were found quite commonly, and were always due to the presence of a congenital sac, because the broad ligament formed part of the sac, which would not likely be the case were the sac acquired. Again, it was commonly noted that in recent herniae the sac was long and narrow, evidently being a preformed canal waiting only distension to form the ordinary bulky blunt-nosed hernia. Finally, the success of the radical cure, which dealt principally and most effectively with the sac showed that the sac was the principal factor in the hernia. Another point of interest in the case was the fact that the boy was treated as an out-patient after his operation. It was not contended that such grown-up children should be so treated, but the opinion that it was safe to operate for hernia upon children who could be carried home was given. The dressing employed was a small piece of gauze quite sealed over by adhesive rubber plaster. By this means the wound was protected from urine and other contaminations. As it was comfortable, there was little tendency for the patient to interfere with it. The dangers of operation for cure of hernia were twofold. First, sepsis; it was as possible to overcome this danger in the out-patient theatre as in the ward theatre. Secondly, the danger of yielding of the stitches because of rough movements after operation on the way home; all such stresses upon the stitches were of trifling moment compared to those accompanying retching or even coughing, and in any case the radical cure depended not so much upon the deep stitches as upon the efficiency of the obliteration of the sac.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.
—At a clinical meeting held on December 18th, 1908, Dr. W. H. CHEETHAM in the chair, the following were among the cases shown: Dr. E. F. TRIVELIAN: *Amyotonia congenita* in a child of 11 months. There was very little movement of all four extremities, and such as was present was almost limited to the hands and feet. Knee-jerks were absent. There was marked hypotonicity of the muscle supporting the head. Some improvement had taken place while under observation. Mr. H. LITTLEWOOD: A boy aged 15 in whom *Cholecystenterostomy* had been performed for traumatic stenosis of the common bile duct

In May, 1908, he was struck in the abdomen and treated in hospital for 15 days. Three weeks later he had an attack of jaundice and vomiting, with recurrence of pain in the right side of the abdomen. In September, second attack of jaundice with great pain. At the operation on October 8th dense adhesions were found round the lower part of the bile duct; the gall bladder was greatly dilated. There were no gall stones. Dr. GORDON SHARP: *Severe Habit chorea* of five years' duration in a boy of 16, following an accident. Very marked improvement took place after one week's treatment with arsenic. Mr. A. L. WHITEHEAD: (1) A case of *Acute otorrhoea* followed by thrombosis of the lateral sinus and internal jugular vein and by extradural abscess, in which a mastoid operation and subsequent excision of the jugular vein was followed by recovery. (2) A case of *Chronic otorrhoea* with extradural abscess and thrombosis of the lateral sinus, the clot extending beyond the torcular Herophili into the sinus of the opposite side, in which similar proceedings were attended by partial recovery. Five months later a large subperiosteal abscess extending over the whole skull was opened and drained, with ultimate complete recovery. Mr. DAVID WILSON: *Angioma* of the face in a man of 24, first noticed three years ago; for the last year discomfort and pain felt in it after exertion or with a cold in the head. The swelling is scarcely noticeable in the erect position, but becomes markedly increased by stooping or exertion. Mr. B. G. A. MOYNIHAN: Two cases in which he had removed the *Gasserian ganglion* for trigeminal neuralgia, with a cure resulting. In the first the large depression at the site of operation was, from the aesthetic point of view, a thing to be avoided; in the second case, the resulting scar, about 2 in. long, was only detectable when specially looked for. Dr. JAMES RUSSELL: A case of abnormal elasticity of the skin. Dr. WARDROP GRIFFITH: A patient with rheumatic mitral and aortic disease, with a "nodal rhythm." There was forcible pulsation on the right side of the neck, with almost total absence of venous pulsation on the left side. That on the right side could be abolished by the administration of digitalis, causing improvement in the tone of the cardiac muscle. Mr. LAWFORD KNAGGS: *Lentiginis ossae* in a girl of 14, with slow progress of the disease since first observed at 6 years of age. A skiagraph showed changes at the base and vault of the skull and in the facial bones. Dr. MAXWELL TELLING: A woman with *Retroclic spasm* of twenty years' standing, commencing at 5 years of age, possibly after measles. The deep muscles of the neck contracted very strongly, and the sterno-mastoids were also involved. There was the usual synergic contraction of the occipito-frontales, with slight twitchings of the facial muscles at the height of spasm. There were almost ceaseless and involuntary movements, in which the hands were raised either to the face or to the back of the head, and these would appear to have developed secondarily as the result of persistent attempts to control the spasm by fixing the head. Mr. MICHAEL TEALE: A man, aged 38, left eye blind since childhood from an unknown cause. When the patient looked straight forward the pupil area of this eye was fairly normal in appearance; but when he stooped a shrunken, white, dislocated lens fell in the pupil.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—At a meeting of the Section of Pathology on December 18th, 1908, Dr. A. R. PARSONS, the President, described a case of *Permieious anaemia* in a man aged 45, formerly a fireman on board a cross-channel steamer. He came to the Extern Dispensary of the Royal City of Dublin Hospital on September 10th, 1908, suffering from weakness and shortness of breath. His appearance was so suggestive of serious illness that he was admitted to the medical ward. On inquiry he stated that four or five months ago he had an attack of influenza, and he attributed the onset of his present illness to starting work too soon, because shortly after resuming work he felt a throbbing in his head, and he felt sick till he sat down. A little later he got headache, palpitation of the heart, and weakness in his legs. In spite of these symptoms he continued at work for five weeks, though he felt as if he had a rope across his chest and abdomen, and as if his head were bursting. He remained at home for ten weeks, but as he was making no progress he came to the hospital. Some of the teeth were carious, and covered with tartar. The spleen was not palpable, and the liver normal,

Definite poikilocytosis, and an increase in the white blood cells was found. On September 25th a blood count showed Hb. 20 per cent., red blood cells, 1,150,000, colour index 0.8. Poikilocytosis was still present. In spite of all that could be done the course of the disease, even during the first fortnight, was steadily downwards. He complained of some pain in his right ear, and on September 26th pus escaped freely from the external ear. His temperature rose to 101° F., the pulse to 120. He became stupid and heavy; his temperature rose to 103° F.; he had a sharp attack of epistaxis. On October 6th he seemed to be a shade better, but on the morning of October 7th he got a profuse epistaxis, and died shortly afterwards. The case might possibly be assigned to the ill-defined group called leukaemia, but the weight of evidence was in favour of pernicious anaemia. Professor O'SULLIVAN said that the appearance of the organs at the *post-mortem* examination was similar to that found in pernicious anaemia, with secondary septic infection. The heart showed well-marked tabby-cat striation, and the liver contained a large quantity of iron pigment. The bone marrow also suggested pernicious anaemia. The blood was remarkable and unusual. The earlier specimens showed a definite polymorphonuclear leucocytosis and poikilocytosis, with very few nucleated red blood cells. The blood films made some days before, as well as those made after death, on the contrary, contained large numbers of nucleated red cells, and a great increase in the number of the white cells. Among the latter were numerous myelocytes. Briefly, the appearance of the organs suggested pernicious anaemia; but the blood removed some days before death was much more like myelogenous leukaemia than pernicious anaemia. Dr. O'CARROLL read notes of a case of tuberculosis of lungs with *Tuberculous tumour in the cerebellum* in a girl of 19, who was admitted to the Whitworth Hospital on May 12th, 1908. From Christmas, 1907, she began to have dimness of sight, and later complained of occipital headache and vomiting. Her sight became worse. There was no relation between the vomiting and food. The tongue was protruded slightly to the right. There was no marked difference in the expression of the two sides of the face. She was quite intelligent; her speech was slow and slightly slurring. There was no discharge from the ears. Both knee-jerks were well marked. There was no actual wasting of flesh, and the menstrual function was right. She improved very much in hospital; but in October, during the speaker's absence from town, she complained of headache, and had bleeding from the nose. Her temperature rose; she became somewhat comatose; and lumbar puncture was performed on November 9th, about 30 c.cm. of fluid being withdrawn. She improved a little for a few hours, but died on November 16th, after several days in a state of coma. Dr. PURSER said that at the *post-mortem* examination the only organs showing disease were the cerebellum and the lungs. The pleura was enormously thickened, and the whole lung was riddled with cavities. It was most remarkable that with such extensive disease of both lungs there should be such slight symptoms. The patient at no time had any cough. Mr. GUNN having read a note on bismuth poisoning, Dr. WALTER SMITH said that, apart from its simple mechanical effects, observations from a physiological point of view showed that bismuth might produce the phenomena of irritant poisoning—just the symptoms to be expected from its alliance with the arsenic and antimony groups. There were several deaths on record, so that it was a drug not to be used recklessly. Dr. HAYES said a good many cases of poisoning had been recorded by radiographers from the use of the subnitrate. Patients had died of overdosing, and the deaths were said to be due to the toxic effects of the nitric acid liberated. The shadow of the nitrate was denser than that of the carbonate.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.—At a meeting in Manchester on December 18th, 1908, Dr. A. J. WALLACE (Liverpool), President, in the chair, the following were among the exhibits and communications:—Dr. LLOYD ROBERTS (Manchester): A fibroid polyp of the uterus undergoing extrusion, removed from a patient aged 39, primipara, who suffered from menorrhagia. Angiomatous changes in its structure were demonstrated microscopically. Miss FRANCES IVENS (Liverpool): (1) Ruptured tubal pregnancy in a young lady married

fifteen months, who had an attack of pelvic pain fourteen days after a normal menstrual period. The pain recurred ten days later, and per vaginam the right ovary was the size of an orange, and some thickening could be detected in the left Fallopian tube. Abdominal section revealed a patent left tube, in the ampullary portion of which a plum-coloured swelling $\frac{1}{4}$ in. in diameter was situated. The left ovary was also cystic and was removed with the pregnant tube. The right ovary formed the larger cyst, but partial resection was possible, and healthy ovarian tissue was left near the hilum. Sections from the middle of the swelling showed the intramuscular site of the ovum. (2) Serial sections of the Fallopian tube in a case of peritubal haematocoele removed from a multipara who had profuse irregular bleeding following a scanty period at the usual time. The undilated tube was found closely associated with a mass of blood clot at its fimbriated end. It was permeable throughout, except at one spot where the lumen was encroached upon by a small mass of organizing fibrin and old blood clot, due to either a tubal mole nearly absorbed or to an incomplete tubal abortion. No traces of chorionic villi could be seen. (3) A tubal mole without haematocoele, occurring in a married woman aged 34, 2 para, in whom six weeks' amenorrhoea was followed by three weeks' moderate haemorrhage. Dr. W. K. WALLS (Manchester): A case of rupture of the uterus. The patient, aged 32, was admitted to St. Mary's Hospital following an abortion, in the treatment of which dilatation of the cervix by tents and the evacuation of the uterus had been performed by her doctor. Several feet of small intestine, separated from its mesentery, protruded from the vulva. Laparotomy and end-to-end anastomosis was performed, but death occurred suddenly on the fifth day. At the autopsy primary healing of the bowel had taken place. Dr. GRIMSDALE (Liverpool): Notes of a case in which a woman aged 42 consulted him a year after marriage on account of dyspareunia. The vagina would only admit the little finger, and that with some difficulty. Dilatation of the vagina was suggested, but was not carried out. Nine months later she returned complaining of symptoms suggesting pregnancy, and on examination it was found that she was three months pregnant, the vagina now admitting the index finger with considerable difficulty. On several occasions during the pregnancy vaginal examinations were made, but the tissues continued to be very rigid. A Caesarean section was recommended and carried out at full term with excellent result to mother and child. Dr. A. J. WALLACE delivered his presidential address, which was devoted to a critical review of methods of dealing with pelvic inflammations, including "Belastung" therapy, and the application of Bier's hyperaemic treatment to gynaecological cases. While admitting the favourable influence exercised by hot-air hyperaemia in non-suppurative disease, he held that the evidence up to the present was decidedly in favour of surgical interference in pus cases. It was also urged that gynaecologists should devote greater study to the prophylaxis of pelvic inflammatory disease.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

At a meeting on December 9th, 1908, Dr. SOLLY (President) in the chair, Dr. BRODRIBB (Hastings), in a paper on *The therapeutic uses of sea water*, said the south coast towns showed great lack of enterprise in the matter. Sea water was largely used abroad for scrofulous diseases and diseases of the female generative organs, and might be applied with advantage in the form of douches, sprays, and brine baths in other diseases, such as rheumatism, joint exudations, glandular enlargements, and some skin diseases. Dr. STREET (Westgate) said that the arguments as to the undoubted utility of treatment by the water of inland spas applied quite as forcibly to that by sea water. In neither case was that value at present fully explicable. Dr. GURNEY (Eastbourne) was of opinion that one important therapeutical point not touched on in Dr. Brodrigg's paper was the fact that in sea bathing there was a mechanical stimulation of the skin by the impact of the spray or surf. The movement of the water gave it an important advantage over the brine baths of inland spas in a certain class of cases. Dr. BUCKLEY (Buxton) considered that the cause of sea-water baths for medicinal purposes would not be advanced by the argument that since sea water contained

more dissolved substances than some mineral springs, it must be more potent. The constituents to which mineral waters owed their undoubted efficacy had not yet been definitely ascertained. Dr. W. J. MIDLTON (Bournemouth), in a paper on *Treatment of rheumatic affections by counter-irritation of the spine*, said he was convinced that continuous counter-irritation in the neighbourhood of the cervical and lumbar enlargements of the spinal cord was a powerful means not only of producing a beneficial effect on the nervous system, but also of eliminating germs and toxins. He had treated 27 cases of polyarticular rheumatoid arthritis in both the early and late stage, 3 cases of paralysis, and 2 of hysteria by this method, with marked success. Dr. LUFF (London) stated that the results of his experience of applying blisters to the region of the spine in the treatment of various diseases of the joints did not compare altogether favourably with other methods of treatment. Dr. ARMSTRONG (Buxton) said that, holding the view that in all cases of arthritis there was more or less interference with the nerve-nutrition of the joints, he had for the last twelve years given special attention to the treatment of the so-called "joint centres" in the cord. After trial of various counter-irritants, he had for the last four years employed electric cautery. The applications, which should not make skin lesions, were made to the sides of the cervical enlargement in affections of the upper limbs, and of the lumbar enlargement where the lower extremities were involved. He did not put this method forward as an actual specific for arthritis, nor did he suggest that it precluded the necessity for careful elimination of all reflex sources of irritation, such as gastric and intestinal intoxications, the various sources of septic poisoning, uterine and general nervous derangements; but he could say that since using this method his results in the treatment of a considerable number of cases of this most intractable disease had shown remarkable and most gratifying improvement. Dr. BUCKLEY (Buxton) said that he had given the methods under discussion a fair trial, and had come to the conclusion that counter-irritation of the skin over the spine, whether by blisters or, as he preferred, by Paquin's cautery, certainly alleviated pain; but he had found no evidence of any curative effect, nor did he think it likely that a disease which undoubtedly was due to bacterial action could be cured by such means. Dr. MANTLE (Harrogate) said he did not favourably regard the treatment. Dr. LLEWELLYN JONES (Bath) spoke in support of the paper.

many leading positions in the British Medical Association and at the Royal College of Physicians, and had been appointed Lumsian Lecturer at the time of his death.

His colleagues have brought together, in a handsome and well-printed volume, a series of original papers dealing with rare and obscure cases and subjects, which will materially aid the advance of knowledge in their respective spheres. Drs. Young and Robinson, Professors of Anatomy respectively at Manchester and Birmingham, present an account of certain malformations of the human heart, suggesting new ideas as to their primary seat and origin. Mr. G. A. Wright contributes notes on some of the less familiar joint affections, with the object of clearing up some of the confusion that has arisen from the indiscriminate use of the term "rheumatoid arthritis," and illustrates, by photograph and description, the lesions produced by other causes than rheumatism, such as septic, gonorrhoeal, autotoxic, and gouty affections. The super-vention of epithelioma on lupus vulgaris is discussed by Dr. R. B. Wild, who explains the present state of knowledge and experience on the use of x rays in such cases. Results as to the healing powers of the rays are at present contradictory, but it has only too clearly been proved that they exercise no prophylactic influence against subsequent cancer when used for the treatment of lupus. Prompt excision of the papillomatous excrescence with which the conversion to cancer is first manifested is insisted upon by the writer. Two short papers—the one by Dr. E. S. Reynolds on intermittent limp, of which five cases are recorded and attributed to the vascular changes in the vessels of the leg, and the other by Mr. Westmacott and Mr. Southam on hyperplasia of the superior maxilla, illustrating the pathology of the disease and marking its distinction from leontiasis ossea—will be found of more than common interest. Mr. William Thornburn contributes a paper on the symptoms produced by cervical ribs, a subject which has only received attention within the last few years, and by the cases quoted and the illustrations appended throws a good deal of new light on the causation of certain nervous and vascular disturbances in the upper limb which have not hitherto been satisfactorily explained. Space will not admit of more than reference to other valuable contributions on cholesterin and cholesterol, on gas-containing cysts, on haemolymph glands, and on many other subjects of interest which are combined to form a worthy memorial of one who left no small mark upon the study of clinical pathology in this country.

Reviews.

A WORTHY MEMORIAL.

THE memory of a tireless worker in the fields of pathological and clinical research has been fitly perpetuated by the issue of a *Memorial Volume* by the colleagues and former pupils of the late Dr. Dreschfeld of Manchester.¹ His death in the midst of professional activity deprived his adopted city and university of one of their most active minds, and the short biography with which the volume opens tells of a lifetime of vigorous and original thought and action, at first in the study of pathology, which was systematically taught in Manchester owing to his influence, and afterwards in the field of clinical medicine, in which he achieved a full meed of success both in public and private practice. Early imbued with the personal teaching of such scientific giants as Kolliker, v. Bezold, Virchow, and Bamberger, he brought a well prepared mind to his work in Manchester, and with it the spirit of scientific enthusiasm without which new ideas are too apt to be ignored. He obtained early recognition. Appointments followed one another in the medical school, and private practice rapidly increased, but he yet found time to contribute many papers to contemporary journals, congresses, and textbooks. No less than 112 such contributions are enumerated in the volume before us. He held

THE FACULTY OF SPEECH.

THE idea with which Mr. MACNAMARA has commenced his book on *Human Speech*² is embodied in the first paragraph of the preface, which states that the object of the work is "to explain the nature and action of the living matter of those parts of our bodies by means of which we gain ideas concerning the external world, and are able to express our thoughts in intelligent speech." Keeping this object in view, Mr. Macnamara proceeds to lay the foundation for his later chapters by a brief discussion of the nature of matter, a short consideration of energy and its transformation, and by defining life as a manifestation of certain phenomena which are the result of chemical and other forms of energy acting on a specific structural arrangement of matter. He then enters into a detailed consideration of the structure and capabilities of living organisms, commencing with bacteria and gradually working up to the highest forms. In the course of this survey he describes how the nervous system originated, and how it has been specialized until it has attained its highest type of development in the human brain. Whilst explaining the phenomena and conditions he describes, Mr. Macnamara lays great stress upon the structure-producing power of function, and he expresses his belief in the transmission of acquired characters. Regarding this point, he says that to deny they are inheritable "is indirectly to say that force does not persist." He further clears his position with regard to this much disputed subject by stating that:

if all parts of an organism have their functions co-ordinated into a moving equilibrium, so that every part perpetually

¹ *Dreschfeld Memorial Volume: Containing an Account of the Life, Work, and Writings of the late Julius Dreschfeld, M.D., F.R.C.P., with a Series of Original Articles dedicated to his Memory by Colleagues in the University of Manchester and Former Pupils.* Edited by E. M. Brockbank, M.D., F.R.C.P. University of Manchester Publications. No. XXXV. Manchester: University Press, 1908. (Roy. 8vo, pp. 246. Illustrated. 10s. 6d.)

² *Human Speech.* By N. C. Macnamara, F.R.C.S. The International Scientific Series. Edited by P. Lerge. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1908. (Crown 8vo, pp. 298; 44 figs. 5s.)

influences all other parts, and cannot be changed without influencing changes in all other parts; and if the limit of change is the establishment of complete harmony among the movements, molecular and other, of all parts, then among other parts that are modified, molecularly or otherwise, must be these which cast off the germ of the new organisms. The molecules of their produced germs must tend to conform to the motions of their components, and to the molecular forces of the organism as a whole, and if this aggregate of molecular forces is modified in its distribution by a local change of structure, the molecules of the germs must be gradually changed in the motions and arrangements of their components until they are readjusted to the aggregate of molecular forces. For to hold that a moving equilibrium of an organism may be altered without altering the movements going on in a particular part of it, is to hold that these movements will not be affected by the altered distribution of forces, and to hold this is to deny the persistence of force.

Whether this argument will suffice to convince the unbelievers is questionable, for they will no doubt be able to bring forward many concrete examples to show that the alteration of the equilibrium of the whole does not necessarily indelibly impress itself on the germ cells, and it is possible they may suggest that, even if the effect of particular conditions acting upon a given individual may cause some modification of its germ cells, it is highly probable that such a modification will be merely temporary, and will entirely disappear when these germ cells unite with others from another individual under conditions which are practically, in normal circumstances, always the same.

The later chapters of the book are devoted to a consideration of the reasons why apes cannot speak, and how the psychical areas of the human brain have become gradually developed through the exercise of the power of expressing thoughts in spoken language. Herein again is expressed the power of function over structure which was shown in the case of the Hydromedusae, whose nervous system is "produced from the living matter of the ectoderm by the action of specific modes of energy stimulating this specialized matter." This being granted, one closes the book impressed with Mr. Macnamara's lucid and interesting exposition of a difficult and intricate subject, but wondering why all the attempts of mammals, other than man, to express their thoughts or impressions to each other have failed to result in the production of speech centres, seeing that, so far as we know, the cellular components of the brains of all are of similar character and are associated with similar sense organs.

THE AURICULO-VENTRICULAR BUNDLE.

In a monograph on the auriculo-ventricular bundle in the human heart, Dr. J. G. MÖNCKEBERG³ gives a careful study of the position and constitution of the muscle fibres that connect the auricles and ventricles. In the introduction he refers briefly to the previous work that has been done in this subject by other observers (except the work of Keith and Flack, which is referred to on page 190) and gives a discriminative criticism of the results. He then proceeds to describe the normal course and histology of the auriculo-ventricular bundle in the healthy human heart, dealing first with its appearance in the fetus. From this he proceeds to describe the bundle at different periods of life, from infancy to old age. It will probably be found that in this part of his work he has laid a reliable standard for the comparison of the healthy bundle with the morbid, although the description throws little additional light on the subject beyond certain variations in the course of the main bundle or its branches. It is of interest to note, however, that in the node (*Knoten*) in the wall of the right auricle he failed to detect any nerve-cells or fibres. He gives a minute and detailed description of the peculiar thread-like fibres that are found passing on the surface between portions of the internal wall of the ventricles. Many of the finer of these threads contain within their endocardial covering nothing but the large Purkinje type of cell. The last portion of the book is taken up with the morbid affections of the bundle and its appearance in cases of lesions of the heart wall. He describes in minute detail the examination of the bundle from the node

to the ultimate division in a large number of different affections of the heart, congenital affections, diseases of the endocardium and the valves, acute and chronic myocardial diseases, and diseases of the coronary arteries. There are ten large plates containing numerous excellent illustrations.

There was a great need for such a work as this, and its appearance supplies a want that has long been felt, for there are now many workers in this field, and this careful study will serve as a guide and a standard. The pathological portion confirms the work of Keith, but there is in this part of the work an absence of clinical details which very materially lessens its value. These careful investigations are really of very little use unless they can be correlated to recognized symptoms during life. Reports of reliable and helpful clinical observations accompanying the description of pathological changes may be considered by the author as apart altogether from his line of work, but the absence of these clinical observations diminishes the value of his book. It should not be necessary at this time of day to insist upon the fact that cardiac pathology can be studied in the living as well as in the dead, and that the evidences obtained *post mortem* are only supplemental to those obtained during life. The fault, no doubt, lies mainly with the clinicians who have supplied him with material, but except in cases of heart-block neither the author nor they seem to have realized that in the careful recording of the movements of the circulation, arterial pulse, venous pulse, apex beat, trustworthy information can be obtained of derangement of function of this auriculo-ventricular bundle, and that for these researches to be of any real value the clinical details are of as great importance as the histological appearance. The absence of an index and the meagreness of the descriptive legends attached to the figures materially lessen the usefulness of the work as a handy book of reference.

SURGERY OF GALL STONE.

THE volume entitled *Drei Jahre Gallensteinchirurgie*,⁴ by Professor KEHR, Dr. LIEBOLD, and Dr. NEULING, contains in its first part the clinical histories of 300 cases operated on in the three years 1904-6. The 500 pages which they fill give detailed notes of the history, symptoms, diagnosis, operation, and subsequent course of each case; and in those cases in which the gall bladder was removed a pathological report is also furnished. One fact strikes the reader at once, and that is the large proportion of complicated cases. This is apparently explainable by the rules which Professor Kehr follows in selecting cases for operation. He still follows those enunciated in his previous publications. In acute inflammation of the gall bladder he operates only when the symptoms are very acute; in chronic cases he intervenes when there are signs of empyema. Cases in which medical treatment is capable of producing subsidence of symptoms he leaves alone, and when there is jaundice and calculi are repeatedly passed he also dissuades from operation. Speaking generally, it is in the case which resists prolonged medical treatment that he recommends surgical measures. These principles, perhaps, also explain the large proportion of cholecystectomies and the small number in which cystostomy was deemed sufficient (6.4 per cent.); they explain these numbers only in part, however, for it is clear that removal of the gall bladder is much more of a routine measure in Kehr's hands than in those of most English and French surgeons. In the case of common duct obstruction he speaks against the adoption of cholecystenterostomy, except in rare instances; he upholds the advisability of drainage of the hepatic duct after the removal of calculi, and in these matters he has the support of most other surgeons of experience. In other matters also, the incision for example, he adheres to his previously published views. His collaborators review the clinical records from different points of view. Dr. Neuling writes on the history and etiology of gall-stone disease. Dr. Liebold writes two chapters on pathological anatomy, including a summary of the microscopical findings in the extirpated gall bladders. From these he concludes that "neither

³ Untersuchungen über das Atrioventrikulärbündel in Menschlichen Herzen. Von Privatdozent Dr. J. G. Mönckeburg, I. Assistent am Patholog.-anatom. Institut der Universität Gießen. Jena: Gustav Fischer, 1908. (Sup. roy. 8vo, pp. 336, 10 plates, and 4 illustrations. M. 25.)

⁴ *Drei Jahre Gallensteinchirurgie*. By Professor Hans Kehr, Dr. Liebold, and Dr. Neuling. München: J. F. Lehmanns, 1903. Roy. 8vo, pp. 735. M. 14.)

cystendysis nor cystostomy, but cystectomy, should be looked upon as the normal method of curing a chronic cholecystitis." The after-treatment of gall-stone laparotomies is the subject of the final chapter by Dr. Neuling. The book will raise again the discussion of cystostomy *versus* cystectomy. An aspect of the question which is not faced here is whether the proper solution is not earlier operation before such ravages have occurred that cystectomy is necessary. A surgeon who operates late will obviously find a larger proportion of cases requiring cystectomy than one who operates comparatively early. Practice will follow principles, and the settlement of the latter guides the former. It is not so much in technique that surgeons differ but in the selection of cases.

PHYSIOLOGY.

Applied Physiology is a welcome little book,⁷ and one can only hope that students in the wards will find time to study it in addition to the ponderous tomes on medicine and surgery which they have inwardly to digest during this stage of their curriculum. Too often the student of medicine imagines that his intermediate medical subjects may be safely forgotten when he has passed his intermediate examinations; this book will prove a useful correction for that idea, and a gentle reminder that what he has learnt in the laboratory has direct applications to what he is learning by the bedside. The various chapters relate to metabolism, animal heat, the circulation, respiration, digestion, and excretion. Dr. HUTCHISON is at his best when dealing with the chemical aspect of physiology, and his very first sentence—"the future of medicine depends on the chemical physiologist"⁸—is no doubt true, but indicates his own predilections. Reading between the lines, we are not quite sure whether there is not a note of dissatisfaction running through Dr. Hutchison's work, a sort of unexpressed feeling that if only physiologists were a little more practical and not quite so scientific, how much better it would be for the clinicians. It is quite true that the gaps in the subject are wide. The nervous system, one notices, is conspicuous by its absence among the chapter headings. On the other hand, it is astonishing how many physiological truths which ought to be reckoned with by clinical observers are entirely neglected by the ordinary practitioner, even by those of the highest standing. A new discovery or a new point of view takes a very long time to filter through into medical textbooks. This is partly due to over-specialization. The clinical observer has but little time or opportunity for reading physiological literature, just as the physiologist so often forgets that his science is, or ought to be, the institutes of medicine. The correlation of the two branches is after all, however, only a matter of time; the younger generation of physicians have a better training in preliminary science than heretofore, and are intensely wishful to make medicine less empirical. Books such as the clear and useful one which has formed the text for these remarks will do much to bring about such a desirable end.

In the preparation of the second edition of his *Lehrbuch der Histologie*, Professor SZYMONOWICZ has obtained the assistance of Dr. Rudolf Krause, of Berlin,⁹ and the result is a textbook thoroughly abreast of the times, both as regards technique and our knowledge of microscopic structure. The illustrations have been increased in number, and all manifest that clearness of drawing and reproduction which formed so important a feature of the book on its first appearance. This relates not only to the illustrations in the text, but also to those which appear in the series of beautiful plates which are bound up with the book. Many of these illustrations will be familiar to English readers, as they have been reproduced in standard works in this country.

We favourably noticed Mr. COLE's *Exercises in Practical Physiological Chemistry*¹ on the appearance of the first

⁷ *Applied Physiology: a Handbook for Students of Medicine*. By Robert Hutchison, M.D., F.R.C.P. London: Edward Arnold. 1908. (Cr. 8vo, pp. 310. 7s. 6d.)

⁸ *Lehrbuch der Histologie*. By Dr. L. Szymonowicz, Professor of Histology in the University of Lemberg. Second edition. Würzburg: C. Kabitzsch (A. Stuber's Verlag). 1909. (Roy. 8vo, pp. 548. Illustrations 325—125 coloured plates. M. 15.)

⁹ *Exercises in Practical Physiological Chemistry*. By Sydney W. Cole, M.A. Second edition. Cambridge: W. Heffer and Sons; and London: Simpkin, Marshall and Co. 1908. (Cr. 8vo, pp. 172. 5s.)

edition in 1905, and we are glad to see that the little book has been successful. In the second edition, just published, Mr. Cole has somewhat extended the exercises, and brought the subject-matter up to date. The course is admirably adapted for serving as a guide in a practical class, and we cannot doubt that the work originally designed for the Cambridge school has been and will be found useful elsewhere.

INCOME TAX.

The increased attention which has now to be paid by the public to income tax is evidenced by the appearance of two new books on the subject. In *Income Tax Simplified*¹⁰ Mr. ARTHUR FIELDHOUSE explains how the annual form of return should be filled in, and gives a summary of income tax rules and regulations, together with a number of worked examples of traders' profits with adjustments for income tax purposes, which will, no doubt, be useful to accountancy students and others. The important points collected at the end of this little book will repay perusal, though the description of Schedule E as the "salary and annuity tax" is somewhat misleading, and the statement on page 40 as to the duties of employers is not in accordance with the provisions of the Finance Act, 1907.

Mr. HALLETT FRY's book on *The Finance Act, 1907*,¹¹ which has now reached a second edition, consists of a reprint of the statute, with explanatory notes and comments on the sections relating to income tax. The author exhibits a considerable acquaintance with the law and practice, and the examples given will be of assistance in making clear a somewhat obscure subject. Advantage might have been taken of the opportunity afforded by the demand for a second edition of this book to bring up to date pages 14 to 17, which contain a print of a form of income tax return that has undergone revision and alteration. The note to Section 20 of the Act does not bring out the important fact that the unit of assessment is still the firm and not the individual partners, the right of partners to be separately assessed having now been expressly repealed. The incomes of individual partners may, however, be treated (but not "assessed") separately for the purposes of a claim for exemption, relief, or abatement. In a note to Section 21 Mr. Fry expresses a hope that "in a proper time" employers may be required to pay their employees' income tax and authorized to deduct the amounts so paid from the salaries of the latter. Probably the Revenue authorities would appreciate this alteration more than the employees.

NOTES ON BOOKS.

THE Society for the Study of Disease in Children, which has recently become incorporated in the Royal Society of Medicine, has issued its eighth volume of reports, edited by Dr. G. CARPENTER.¹² They make a handsome volume of some 500 pages, adequately illustrated in black and white and in colours. The report of the annual general meeting is illustrated by photographs of Dr. Henry Ashby of Manchester, Dr. C. Nelson Gwynne of Sheffield, and Dr. A. E. Sanson of London, all, we believe, original members of the society, whose deaths had occurred since the last report. The society has done well to complete its publications by the issue in a separate volume of a *General Index*¹³ of the eight volumes of reports which it has published.

Dr. WEISS, in his compact little pamphlet on *Newer Methods for the Qualitative and Quantitative Analysis of the Urine and Gastric Juice*,¹⁴ has not sought to put before the practitioner an exhaustive account of the methods

¹⁰ *Income Tax Simplified*. Being a guide to the preparation of the Return for Assessment, and a practical and authoritative exposition of the Finance Act, 1907. By Arthur Fieldhouse, Accountant and Auditor, etc. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1908. (Demy 8vo, pp. 41. 1s.)

¹¹ *The Finance Act, 1907, in its Relation to Income Tax*. By T. Hallett Fry, Barrister-at-Law. Second edition. London: Stevens and Sons, Limited. 1909. (Demy 8vo, pp. 108. 2s. 6d.)

¹² *Reports of the Society for the Study of Disease in Children*. Vol. viii. Session of 1907-08. Edited by G. Carpenter, M.D. (Demy 8vo, pp. 592. 12s. 6d.)

¹³ *General Index to the Reports for Vols. I to VIII, 1900-08*. London: J. and A. Churchill. (Demy 8vo, pp. 102. 3s. 6d.)

¹⁴ *Newer Methods for the Qualitative and Quantitative Analysis of the Urine and Gastric Juice, performed easily, rapidly, and accurately by the General Medical Practitioner*. Compiled by Richard Weiss, M.A. Ph.D., F.C.S. London: The Robson Company. (2s. 6d.)

used, but has described plainly the steps by which each investigation should be carried out, investigations which may be looked upon in some cases as giving a definite answer, in others as merely indicating some further and more careful work. The various reagents, glasses, and apparatus are compact and cleverly devised, and if, as is the case in the fermentation test for sugar, they require some manipulative dexterity, the latter does not seem to be beyond the powers of any modern practitioner.

The latest fasciculus on the *Proceedings of the Royal Society of Medicine* is dated December, 1908, and covers one or more meetings of thirteen sections. Among these, one, that of anaesthetics, is new; its work was inaugurated by Mr. Richard Gill, its president, in an address on chloroform action. The account of the work of the surgical section contains a paper by Mr. Keetley dealing with the questions of why and how to attempt to preserve the appendix.

MEDICAL AND SURGICAL APPLIANCES.

A Percussion Hammer.

DR. EDGAR CYPIAX (London) writes: A percussion hammer, designed by Dr. Emil Kantorowicz, of Berlin, is constructed on the principle of the ordinary sliding-weight weighing machine, which has two arms of unequal length. If the attached weight be moved along on one of these arms away from the other arm, the greater will be the tendency for the former to descend rapidly; in other words, its momentum will be increased, and vice versa. As the accompanying sketch shows, the nearer the sliding weight is moved towards the percussion end of the hammer the greater will be the impact of the instrument on the finger that has been placed over the area to be percussed, and it thus becomes possible accurately to regulate the force of the stroke. The instrument is more fully described in the *Medizinische Klinik* of September 13th, 1908, and can be obtained from the makers, Messrs. Dewitt and Herz, of Berlin.

Half natural size.

(the stomach or intestines cannot be brought out of or into the parietal incision, the clamps in ordinary use are practically valueless, but by means of the right-angled shoulder in my clamps it can be placed effectively inside the abdominal incision. I have used them successfully in extensive resections of the stomach.

of the colon, and of the small intestine, and end-to-end or lateral anastomosis was completed with precision of juxtaposition of the parts. In cases of gastro-duodenostomy or jejunostomy, where one is obliged to work under the costal angle, I have found them specially useful. In ileocolostomy, where the junction had to be made near the brim of the pelvis, the handle of the clamp rested upon the left thigh. The blades are 5 in. long, in order to meet every possible condition of the parts to be joined together, and the points are prevented from overriding by points like those in the Gelston Atkins twin anastomosis forceps.

¹³The *Proceedings of the Royal Society of Medicine*. Vol. II. No. 2. London: Longmans, Green, and Co. (Price 7s. 6d. net.)

Chloroform Tube Terminal for use with Brüning's Bronchoscope.

Mr. H. BELLAMY GARDNER (London, W.) writes: Messrs. Allen and Hanburys (Wigmore Street) have made for me a blackened German silver tube with flattened concave end for the delivery of chloroform vapour from a Junker's bottle when Brüning's bronchoscope has been passed through the vocal cords into the trachea or one of the bronchi. By means of this terminal, which at its end is concentric with the orifices of the various portions

of the specula of the bronchoscope and has also a short flange for steadying it in position, chloroform anaesthesia may be suitably maintained without interference with the surgeon's view from the eyepiece or the manipulation of instruments within the speculum. Its blackened surface of nitric bronze does not reflect the light of the electric lamp, and is practically invisible through the instrument while in use.

The "Forsyth" Sling-Pillow.

A sling-pillow has been devised by Mr. Cairns Forsyth for keeping patients in the semi-recumbent and "Fowler" positions. Propping-up by pillows alone is not sufficient, as the patient slips down from his own weight. Several methods have been tried to overcome this. The above-mentioned "sling-pillow" is one of these. The patient is well propped up by means of pillows or a bed rest. The sling pillow is placed under the thighs, and the straps

MEDICAL SUPPLY ASSOCIATION

fastened to the top bar of the bed head. In this way the body may be raised at any angle. It is claimed that this sling-pillow will be found useful in the after-treatment of cases of abdominal section, especially those in which the operation has been in the upper abdomen, and in nursing cases of pneumonia, bronchitis, and pericarditis. The pillow is made by the Medical Supply Association, 228-230, Gray's Inn Road, W.C.

MEDICINAL AND DIETETIC PREPARATIONS.

Sabromin.

FOR the purpose of administering bromine without the employment of bromides, with a view to avoiding the by-effects known as bromism, calcium dibromobehenate has been introduced by Messrs. Meister, Lucius, and Brüning (51, St. Mary Axe, London, E.C.). This compound has received the name Sabromin, on the analogy of the name Sajodin, which is in use for the corresponding iodine compound. It is a white powder, insoluble in water or alcohol, and free from taste and odour. It is also supplied in the form of tablets containing $7\frac{1}{2}$ grains: specimens of these which were submitted were soft and easily powdered, but did not disintegrate when placed in water.

AUSTRALASIAN MEDICAL CONGRESS.

(Continued from p. 30.)

WORK IN THE SECTIONS.

Section of Obstetrics and Gynaecology.

THE work done in this Section was of an attractive character, obstetrical questions considered being for the most part of general interest. The officials of the Section had arranged with some recognized authority to open a discussion by means of a short paper on each day of the session, with the gratifying result that keen interest was displayed by country members, who contributed to the debates the experience gained in lonely country practice. The President of the Section, Mr. E. T. THRING, F.R.C.S. (Sydney), opened the sectional proceedings with a short address in which the position gynaecology held in relation to general abdominal surgery was passed in review. The enlargement of the field of the gynaecological surgeon so as to embrace the whole abdomen was advocated as tending towards advancement. An earnest appeal was made for thoroughness in operation work, and that the time factor should not be unduly strained, on the one hand by "lightning operations," and, on the other, frittering away valuable minutes on useless manipulations. Extensive anatomical and sound pathological knowledge, with less slovenly surgical technique, were urged as essential to the equipment of the abdominal surgeon of to-day. In concluding his address, the President referred to the work of Sargent and Dudgeon on the "bacteriology of the peritoneum," pointing out that the more gynaecologists and obstetricians knew about bacteriology and serum therapy, the more competent they would become to cope with the infectious processes associated with the peritoneum and parturition. Dr. J. A. G. HAMILTON (Adelaide) initiated a discussion on fibroids by a short paper in which he referred to the increasing knowledge regarding the frequency with which degenerative changes occur in these growths, more especially about the climacteric period, and urged an early removal. Dr. G. HORNE (Melbourne) followed with a paper in which he discussed the influence of pregnancy on fibroid growths of the uterus, and instanced cases where the growth practically disappeared during pregnancy. He advanced some ingenious views regarding the causation of myomata. Dr. RALPH WORRELL (Sydney) opened a discussion on the causation, results, and treatment, immediate and remote, of injuries of the genital tract, laying stress on the importance of immediate repair of injuries of the pelvic floor following parturition. Dr. FELIX MEYER (Melbourne) introduced a discussion on the indications for prematurely terminating gestation. He remarked that, conditions being favourable, labour obstructed by pelvic contraction or tumour should be terminated by operative measures in the interests of the child, and that for practical purposes the consideration of the premature termination of gestation might be confined to the toxæmias of pregnancy. Many speakers advocated early emptying the uterus where the symptoms were progressive and did not readily respond to treatment. Dr. CHENHALL (Sydney) read notes and showed photographs of a case of actinomycosis of the female generative organs. Dr. MARY DE GARIS (Muttaharra, Queensland) read notes on a case of anencephaly with face presentation. Dr. F. A. NYULASY (Melbourne) showed lantern views of "Polypoid endometritis, a frequent and dangerous complication of pregnancy and the puerperal state." Dr. T. G. WILSON (Adelaide) opened a discussion on early recognition and treatment of pelvic infectious processes in the puerperium. He approved of the idea that a temperature remaining above 101° F. for two days should be taken as symptomatic of sepsis. Alterations in temperature, pulse-rate, involution of the uterus, and character of the lochia, were the means by which sepsis could be early recognized, increasing knowledge of these infectious processes tending to show the futility of making any sharp differentiation between saprophytic and septic infection. Dr. WILSON urged the importance of making a thorough examination to ascertain whether the uterine cavity was clean or not at as early a date as possible. If the uterus was thought to contain anything it should be carefully curetted and an antiseptic thoroughly applied to the walls, the uterus being subsequently packed with gauze soaked in the antiseptic. In advanced cases he advocated the trial of vaccines.

Section of State Medicine.

The President of this Section was Dr. J. M. MASON, Chief Health Officer of New Zealand, who in the course of an address recorded much progress in that State. In New Zealand the attitude towards public health had greatly improved. There was now no such thing there as a part-time health officer. No man, however important he might be, could now depose the medical man who had dared to condemn his property. While moralists were wringing their hands and there was general regret over the increased reluctance of parents to have children, the true friends of the State were urging that greater care should be taken of those children that were born in New Zealand. The State had established in each of the large centres hospitals where respectable women of the working class could go to be confined. These hospitals were well appointed, and staffed by nurses specially trained in midwifery. Instead of staying up-country far from medical aid, the wives of hardy, reliant pioneers now came into town and received the very best attention. So, too, did the wives of workers in the city. The charges made were of a kind that such people could pay, and the cost to the State was small. The net result was that not only were the mothers protected, but the children were well cared for and got a good start in life. In nearly all cases the mothers had been persuaded to suckle their children. Large increases had been made in the number of dairy inspectors, and a New Zealand municipality had the power to say "No one shall sell milk in our borough unless it has passed through our conduit and has been certified as pure and wholesome by our Health Department." In regard to vaccination, he asked whether it was worth while to continue to maintain a large staff of registrars and inspectors merely for the registration of exemption certificates. Last year in New Zealand, out of 24,321 children born, only 4,486 were vaccinated, and 2,964 were exempted. The balance of 16,871 were not accounted for. The time had come when either parents who had neither had their children vaccinated nor obtained exemption certificates should be brought before the magistrates as a matter of routine, or the law should be altered so that all semblance of compulsion should cease. It was unfair to expect officers of the Health Department to control an outbreak of small-pox if the weapons on which they most relied were denied them.

In the State Medicine Section an address was given by Dr. R. ARTHUR (New South Wales) on "The Colonization of Tropical Australia." It was, he said, a subject on which the medical profession was in a better position to give a pronouncement than any other. He had no quarrel with what was popularly known as the "white Australia" policy; rather he applauded it as embodying a splendid ideal by which a great area of the earth's surface should be reserved for the building up of a community which would be the flower of modern civilization. Unfortunately it did not follow that because a thing was desirable it must necessarily come within the realm of the practicable. About one-third of Australia was within the torrid zone, and various attempts to implant convict settlements in the Northern Territory early last century had been abandoned after a few years' trial of the climate. It was a significant fact that after nearly fifty years of administration by South Australia, the Northern Territory, which was four times the size of Great Britain, had a population of only 680 male and 200 female Europeans. There must be some potent reason for this disinclination of the Anglo-Saxon to go north, and the probable explanation was that no one would suffer gladly a climate which kept between 90 and 100 degrees for months, unless exceptional opportunities for making money were offered to him, and this did not appear to be the case in tropical Australia. On the contrary, the cry was for cheap labour to develop the tropical industries which were carried on by poorly-paid labour in other countries. The all-important issue was, "How can the women and children of a white race thrive there, and what will be the physical condition of the second or third generation of the native-born?" Most enthusiastic accounts of the health of the children under his observation had been given by one medical man, who stated that the people of North Queensland seemed to revel in the heat. On the other hand, Dr. Frederick Goldsmith, who resided for five years

in Port Darwin, wrote in a most pessimistic manner about the possibility of acclimatization, and supported his belief by a wealth of personal experience. Therefore, while reluctant to abandon the ideal of a white Australia, the speaker felt himself forced to the conclusion that a large Anglo-Saxon settlement in Northern Australia was impossible. It would be true wisdom for the Commonwealth authorities to institute a searching examination into the subject before proceeding to any practical steps towards settling people in Northern Australia. In conclusion, he moved that it be a recommendation to the Congress that a deputation approach the Prime Minister and request him to appoint a Royal Commission to inquire into the possibilities of the colonization of tropical Australia by the Anglo-Saxon or other white races. This was seconded by Dr. W. RAMSAY SMITH (South Australia) and passed. Dr. GERTRUDE HALLY (Hobart) gave an account of medical inspection work amongst school children in Tasmania, which was almost commercial in its object, its ultimate aim being to detect children who were physically unfit to benefit by modern educational methods, and improve school conditions for them. Direct treatment was never undertaken. Parents were informed as to the defects found, and advised to submit the child to their own medical attendant. Teachers were also advised concerning the hygienic management of their schools, and as to school care of any particular child. The procedures in city and country schools necessarily differed. In the former the two part-time inspectors visited at least once weekly. They examined all new scholars, and visited the classrooms regularly, when any child who appeared "out of sorts," or displayed any skin eruption, was picked out for special examination. The examination on entering school comprised the usual physical details of height and weight, acuity of vision and hearing, and the like. A history of previous illnesses was recorded briefly, and was of considerable practical value in enabling non-immunes to be sorted out for exclusion in the event of an outbreak of the ordinary communicable diseases. Details were entered in a card index. Spaces were left on the back for entering up the subsequent annual increase in height and weight, with notes of the children's annual progress and condition. The routine work was done by a teacher, the medical inspector seeing the child, and, if necessary, checking the teacher's observations. Defective children were entered up in a register, together with notes of advice given to the teacher. When the defect was likely to interfere with the educational progress of the child a notice was sent to the parent. This memorandum did not exempt the child from attendance from school. Should the child, however, be suffering from an infectious disease another form of notice was sent by parents. Copies of notifications of infectious diseases occurring in city districts were forwarded by the Department of Public Health to the medical inspectors. In the event of an outbreak appearing to be connected with a school the necessary steps for exclusion of cases and contacts, etc., were taken under the direction of the chief health officer. Last year what would probably have been a serious school outbreak of diphtheria in Hobart was prevented in that way. In Tasmania they did not close the schools for outbreaks of infectious disease, but depended on the more rational methods of systematic exclusion. As regarded country schools, a general survey was first made of the rooms and children, such salient details as working positions, grading in desks, general cleanliness and management of the room being specially noted. The card index system had not been introduced into country schools, a model register only being used. Each child was weighed and measured. Vision and hearing were tested, throats examined. Should any child appear delicate, or give a history of rheumatic or scarlet fever or chorea, a further examination was made of their chests. When heart trouble was present special instruction was given in regard to physical exercises and drill. The best available methods of improving the existing condition of things were pointed out to the teacher. Perflation and ventilation were explained, together with the advantages of sweeping with damp sawdust and damp dusting as opposed to "dry methods." In no case was the educational work of the school interfered with, except, perhaps, in such a case as when the suggestion was made that the desks should be turned so as to get left-side instead of back light. At the

lectures at the training college the advantages of a timetable arranged on rational hygienic lines were pointed out. As regarded results, between March, 1907, and June, 1908, some 11,287 children were examined. Of these 4,158, or 36.83 per cent. of all children, were defective to an extent interfering with, or likely to interfere with, their educational progress.

Special Sections.

The Section for Diseases of the Eye, Ear, Nose, and Throat met under the presidency of Dr. LOCKHART GIBSON (Brisbane), who opened a discussion on syphilis, noting the special facilities afforded by the structures of the eye for the study of this disease, and of the effects of treatment, emphasizing the low value of negative histories, and making clear the frequency with which syphilis is met in practice. A paper on interstitial keratitis, by Dr. J. P. RYAN (Melbourne), led to an interesting discussion on syphilitic eye affections in general. Mr. A. L. KENNY (Melbourne) showed seventy-three lantern views of the interiors of clinics in Europe, Asia, and America; and Dr. LINDSAY MILLER (Hobart) showed views of an Egyptian travelling ophthalmic hospital. Other papers on eye diseases were read by the PRESIDENT, on an operation for entropion; Dr. J. P. RYAN, on the diagnosis of trachoma; a pathological report on sarcoma of the iris by Dr. MILLER. Dr. MAHER (Sydney) opened a discussion on the prognosis and treatment of glaucoma, describing his operation for a permanent cystoid cicatrix. Dr. PAEST (Auckland) showed a mattress suture used by him in the extraction of cataract. The ear, nose and throat work included a discussion opened by Dr. BRADY (Sydney) on the treatment of deformity of the nasal septum. He recommended the use of Bosworth's saw and Carmalt Jones's spokeshave, and indicated the proper sphere for the submucous resection known as Killian's; he also showed for Dr. RUSSEL NOLAN (Sydney) some admirably prepared dissections of the temporal bone to illustrate the facial nerve relations to the radical mastoid operation. Dr. KENT HUGHES (Melbourne) read a paper on some points in the anatomy and surgery of the accessory sinuses of the nose, and showed some views of irregularly situated cavities. Dr. EWING (Melbourne) gave reasons for the selection of the intrameatal and tympanomeatal mastoid operation in the operative treatment of chronic suppurative of the middle ear. On the motion of Mr. KENNY, seconded by the PRESIDENT, it was resolved that the Section express its appreciation of the long-continued, original, and epoch-making work in the investigation of the causes and the best methods of treatment of diseases of the ear by Hofrath Professor Doctor Adam Politzer of Vienna, and offer to him on his retirement from his professorial chair in the University of Vienna the homage of its respectful admiration.

In the Section for Radiotherapy and Diseases of the Skin, a paper was contributed by Mr. A. W. FISCH NOYES on the relative proportion of various skin affections in Australia. His conclusions, drawn from an analysis of 5,000 cases of skin disease, were that no affections of the skin existed in this south-east portion of Australia which had not been observed in English clinics. The frequency of occurrence, however, of some affections differed considerably when compared with English figures, but the difference was no greater than was seen between statistics collected in London and those compiled in Scotland. The types had not as yet been developed to any appreciable degree either by climate or other surrounding influences. Dr. ALEXANDER ROBERTSON of the Gilbert and Ellice Island Protectorates, where yaws is common, contributed an interesting paper on the transmission of this affection, and detailed the main points of differentiation between it and syphilis. There were differences in the appearance of the eruption, including absence of polymorphism, the more rapid response amongst the Gilbertians to iodide of potassium, the absence of such concomitant symptoms as throat lesions, alopecia, and iritis. The ulcers had not the "punched out" and other characteristics of syphilis. Gummata and periosteal thickenings were not found in yaws, though they were common amongst the Gilbertians who had contracted syphilis. Yaws was never congenital, and occurred afresh in those who had become protected against syphilis by a previous attack.

The Concluding Session.

The last work of the Congress was a general meeting, at which sundry resolutions passed by different sections were considered and dealt with. The more important resolutions adopted included recommendations to the effect that a uniform system of physical inspection of school children should be adopted by all States, and that there should be an annual conference between professional heads of the State health departments in Australasia, in order to secure better co-operation in hygienic effort. Other resolutions confirmed advocated the provision of a seat for a medical expert on all naval and military boards and councils of defence, and urged that all health authorities and hospital committees should take steps to provide adequate protection for x-ray workers, and that medical men as a whole should take care to consult with regard to x-ray work only qualified medical men. Finally, it was resolved to hold the next Congress in Sydney in 1911, and Dr. Antill Pockley, of New South Wales, was unanimously elected its president. A number of votes of thanks, including one to the President and Mrs. Allen, then brought the proceedings to a close. During the progress of the Congress a good many entertainments were given, the most important being a dinner given by the Victorian to the visiting members of Congress. At this Professor Allen presided, and Sir Thomas Carmichael, the State Governor, and Sir John Madden, the Lieutenant-Governor, and many of the principal Ministers were among the guests.

LITERARY NOTES.

MESSRS. MACMILLAN will, it is announced, publish in the course of the present month a book entitled, *Faith and Works of Christian Science*, a critical examination of the gospel according to Mrs. Eddy by the author of *Confessio Medici*.

The Walter Scott Publishing Company, Ltd., is about to issue a work entitled *Infant Feeding*, by a Physician, in their "Useful Red" series of shilling books.

The fact is perhaps not generally known that the famous Florentine preacher, Fra Girolamo Savonarola, began his career as a student of medicine. He came of a medical family, his grandfather being Michele Savonarola, a celebrated physician of Padua, who was invited to fill the chair of medicine at the University of Ferrara by Duke Nicolò the Third of Este. Michele's son became Court physician to Duke Ercole, and rapidly dissipated the large fortune amassed by his father. It was in the hope of restoring the fallen fortunes of the family that the young Girolamo, Michele's grandson, was destined for a medical career, and his early studies were directed by his grandfather. Girolamo, however, hated Court life, and was disgusted by the wickedness he saw around him. In 1474, at the age of 22, he threw up his profession, and left his home at Ferrara secretly to enter the monastery of San Domenico at Bologna.

The *Rivista di Scienza* ("Scientia"), an "International Review of Scientific Synthesis," published in Milan, enters on its third year of journalistic life in 1909. The objects of the periodical are to deal with general questions relating to the sciences and their mutual relations and to co-ordinate the work done in the different fields of science and facilitate its synthesis. Articles are published in the language of their authors; but, commencing with 1909, the text of the Italian, English, and German articles will be accompanied by a supplement, with the translation in French. The Editorial Committee consists of Signori G. Bruai, A. Dionisi, F. Enriques, A. Giardina, and E. Rignano. The periodical can be procured in this country through Messrs. Williams and Norgate.

To the *Journal of the Royal Army Medical Corps* for December, Major F. W. Begbie contributes an interesting note, with illustrations, on the buried cities of Ceylon. In order to follow the history of those cities, he says, it is necessary to go back as far as the middle of the sixth century B.C. It was at that date that Ceylon, or Lanka, as it was then called, was first inhabited. Very little is known of the history of Ceylon at that period beyond the fact that the island was constantly being invaded from India. Sometimes the invaders were victorious, sometimes the "Sinhalese." These wars continued till the end of the fourth century before Christ, when King Devanampiya-Tissa occupied the throne of Ceylon, the

city of Anuradhapura being his capital. At that time King Asoka reigned in India, his head quarters being at Magadha, 200 miles from Benares. At the beginning of the third century B.C. Asoka sent his son with two Buddhist monks to Ceylon to propagate the Buddhist faith. They converted the king and his followers, who in turn converted the people. To commemorate this event the first of the enormous dagobas, which form a large portion of the ruins of the buried cities, was built close to the capital of Anuradhapura. It was built over the left collar-bone of Gotama Buddha, a precious relic which the King of Bengal had bestowed on his royal brother of Ceylon. Of the 167 original pillars surrounding the dagoba, only 37 now remain; they are supposed to be the remains of a roof built over the dagoba in 119 B.C. They are slender monoliths of beautiful proportions, and are now as they were in 300 B.C. The ruins of the buried cities cover a distance of 16 square miles, and the city was then, as now, divided into two portions, the "Sacred" and the "Political." The modern excavations were begun when Sir William Gregory was Governor, some thirty years ago. Major Begbie gives a description of the ruins, with their temples, pillars, statues, etc. The Temple of Kandy was built to contain the tooth of Buddha. In the centre of this temple is a small chamber containing a huge silver dagoba. This dagoba has six inner shrines, each studded with gems, the doors of which are opened by six different keys kept by six different persons. Inside the innermost shrine, upheld on a twist of gold wire arising from the centre of a golden lotus blossom, is seen the tooth of Buddha, which is an object of the greatest veneration to 400,000,000 people.

In seconding a vote of thanks to Dr. T. Gillman Moorhead, whose sketch of the history of medicine, delivered as an inaugural address at the opening meeting of the Dublin University Biological Association, was referred to in this column in the *JOURNAL* of December 26th, 1908, Professor Mahaffy said he had made a special study of the lives of some great Irish physicians. Among those mentioned by Dr. Gillman Moorhead was John Stearne, who was instrumental in procuring the first charter incorporating the College of Physicians in Ireland. Professor Mahaffy, who said he had read through all Stearne's works, thought Dr. Moorhead had estimated too lightly his contributions to medicine. From Hippocrates, Stearne had learned the vanity of charms and incantations. He went back to the great natural principles of the Hippocrates school: (1) No diseases were specially divine diseases, but all equally natural; (2) that medicine should start not from pathology but from hygiene. The first rational doctors were those who discovered wholesome food for men, who cooked meat, who crushed corn, who selected wholesome vegetables. Hence were discovered the laws of health, and from the violation of these laws, in general, came disease. Hence the famous tract, *De aëre, locis et aquis*—"Site of a city, its aspect and its water supply." And if these precautions failed, what next? As they saw in his works, the third step was a careful clinical observation of individual cases with all their symptoms as a guide to future men, so that they had in his Greek extracts descriptions of typhus fever, of puerperal fever, and other such diseases, so careful and scientific that they could be recognized at once among them. This was the school of Stearne. They had lost his clinical observations, which must have been minute and careful, as well as his prescriptions, which were few, for there was little use of drugs in that sensible school, but they had observations on hygiene which were not antiquated to-day. Hippocrates had announced that every physical organ required exercise, or else it was liable to atrophy. Stearne recommended variety as the essence of a sound life; but he told them that violent exercise, though very good for health, by no means induced longevity, and that a monastic life of simplicity and monotony produced longevity and not necessarily health. Among the few drugs he recommended was the use of tobacco. Stearne's great medical book was on the nature of death—what it is, and whether it was inevitable. He would like to explain to them his theory. As he thought the Tree of Life which would have kept Adam alive for ever a natural tree—possibly still existing, though unknown—so he thought the exceptional lives of the Patriarchs were rare instances, which, if the rule, would have made the world impossible to stand on.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT.

(Continued from page 44.)

WE continue our abstracts from the evidence of which the minutes are contained in the fourth report of the Royal Commission on Vivisection, issued in December, 1907.*

Evidence of Professor Rose Bradford, F.R.S.

DR. ROSE BRADFORD said he had sent in a short summary of the evidence he wished to give. He had divided it into two groups—one dealing with the results obtained in the various committees on which he happened to serve, especially those in connexion with the Royal Society, the other with the use of experiments on animals in the practical work of the physician. In that he had mentioned two or three instances in which he thought the physician in his everyday practice was directly dependent upon the methods he had to employ, involving experiments on animals to obtain the knowledge necessary for the treatment of the sick. For instance, there were many diseases which in the early stages could not be detected by physical examination of the patient, but they could be detected by methods of investigation necessitating experiments on animals. There were classes of cases in which the only satisfactory method of determining whether the patient was or was not suffering from tuberculosis was the inoculation of a guinea-pig with the material expectorated by the patient. He had had the experiments done on several occasions when there was some doubt whether the patient was suffering from tuberculosis or from bronchiectasis. He also quoted diphtheria and typhoid as illustrations of acute diseases in which experiment was useful for diagnostic purposes. In a case of suspected diphtheria the modern diagnosis was made by recognizing the organism. The foundations of their knowledge as to the organisms were derived from experiments which in the past involved experiments on animals—as, for example, to determine whether an organism was virulent or not. In cases of diseases of the bladder and of the kidney it was often extremely difficult to be absolutely certain that tuberculosis was present without an inoculation experiment. In reply to the Chairman, the witness said he attached great importance to the freedom of the physiologist to experiment upon different kinds of animals. First, because he thought that, in order to obtain a really sound knowledge of physiological processes, one wanted to have the opportunity of investigating them under different conditions. Some animals resembled man more closely in certain parts of their structure and functions than others. For instance, the general nutritive processes in the dog had a closer analogy to those in man than in the case of many other animals. Asked if there were any purposes for which he considered the dog essential, he said it was very difficult to carry out experiments on the circulation in other animals than the dog. The dog was the animal in which the circulatory apparatus had much more resemblance to that of man than in the case of many other animals. Then there were the digestive processes and the nutritive processes generally. Asked by Dr. Gaskell if he would include in the circulation the lymph system, the witness replied in the affirmative. If dogs were excluded from experimentation it would cripple physiology in this country to a great extent. He thought demonstration by experiments essential for the proper education of students. The demonstrations must, of course, be on anaesthetized animals, which were killed before they recovered from the anaesthesia. Asked if he had ever known of animals being vivisected for purposes of demonstration (cut into with the knife for purposes of demonstration before students) without anaesthetics, he said he never had. Sir William Church asked about the following passage in the evidence of Mr. Graham:

I only propose to give just one or two cases, so that my argument may not be in the air. Dr. Rose Bradford cut into the ears of dogs, destroyed the tympanic plexus, scraped out the middle ear, and poured in pure carbolic.

Dr. Rose Bradford said he was written to by the Secretary of the Commission with reference to this matter, and he had sent in a statement already with reference to it. These experiments were experiments on the physiology of secretion from the salivary glands—experiments on nervous regulation of secretion which involved the cutting of nerves supplying certain glands, the submaxillary gland and the parotid gland. The nerve going to the submaxillary gland was, of course, easily divided, the nerve going to the parotid gland could not be readily divided, and so, in order to destroy that nerve the ear was opened, under anaesthetics of course, in the usual way in which a surgical operation on the ear was performed, and the interior of a certain portion of the ear was rubbed with a spoon, and then 1 minim of pure carbolic acid was allowed to run in, and was then wiped up with a piece of cotton-wool and the wound was closed. The object of the operation was to divide or destroy the nerves supplying this particular gland. These experiments were done under Certificate B. It was put to the witness that Mr. Graham went on to say that the operation was done under chloroform, but the dog lived for weeks afterwards in what must have been a condition of great suffering. Dr. Rose Bradford replied that there was no evidence of suffering at all. It was a common surgical procedure to scrub wounds with pure carbolic. It was, if anything, rather painless than painful. Pure carbolic acid used in that way destroyed what it was in contact with and did not, therefore, lead to any subsequent sloughing or inflammation when used in a small quantity like that, and was applied in the form of one drop locally. It was a very powerful local anaesthetic. It was applied, for instance, to a painful tooth to destroy the nerve. He thought the experiments referred to entailed no more suffering than obtained in the healing of any healthy wound. The witness was then asked about a statement made by Mrs. Cook that he performed various operations upon the kidneys of dogs at the Brown Institute. She went on to say:

Chloroform and morphia were used for the actual operation, and the animals were then placed in a glass case, with a glazed floor, for observation. Pieces were cut out of the kidneys, and they were mutilated in different ways. In the case of one dog, the operator cut a piece out of a kidney, and then tried to graft the piece and make it grow on another part of the inside of the animal. The animal died in four days.

Dr. Rose Bradford replied that those experiments (which were not done at the Brown Institute) were begun in 1889, and went on for six or seven years. The object of them was to see whether it was possible to produce in animals, by diminishing the amount of kidney substance, a slow poisoning at all akin to that seen in Bright's disease. A number of facts were observed in the course of these experiments, perhaps the most important being that nothing at all akin to Bright's disease was produced by the diminution of the kidney substance. A considerable amount of valuable information was obtained. Thus, accurate information was got as to how much kidney was necessary for the maintenance of life. That affected prognosis. It might also conceivably affect operative interference. Another thing that he thought of some value was that it gave one a different idea of the significance of the quantity of urine that was passed. There were certain conclusions in human medicine that were drawn from a person passing much or little urine, and he thought those experiments showed that at any rate other factors had to be taken into consideration. But the most important thing of all was, he thought, that no such condition as that known as human uraemia was produced. Asked what became of these dogs, the witness said the Commissioners had had a copy of the published paper giving the facts as regarded each one. Summarizing the facts, he would say that a great number of these dogs lived for very prolonged periods in perfect health, without apparent suffering. Some lived, for example, for two years, and they were killed, not because they were ill, but because it served no useful purpose to keep them any longer. Others wasted; they passed large quantities of urine and got thin, but they suffered no more than that. Others, where the quantity removed was greater, got so thin that they became extremely weak, and no doubt ill; they vomited occasionally; and those animals were killed immediately. Some of them, as stated by Mrs. Cook, died within a few days of the operation. He remembered the one alluded to as

* London: Printed for His Majesty's Stationery Office, by Wyman and Sons, Limited, 102, Fetter Lane, E.C. And to be purchased, either directly or through any bookseller, from Wyman and Sons, 102, Fetter Lane, Fleet Street, E.C.; and 32, Abingdon Street, Westminster, S.W.; or Oliver and Boyd, Edinburgh; or E. Ponsonby, 115, Grafton Street, Dublin. (1908.)

having lingered thirty-six days, because it was a very remarkable one. That animal died suddenly—he did not know from what cause—but the facts as regarded each individual were fully published. On its being put to him that only two died from blood poisoning as the result of wounds, and one in four days, he said he had no doubt that was true. The others were much in the condition of a man who had had a successful operation performed upon his kidney after he recovered. There was no truth in the statement that they were suffering tortures or pain. The only ones in which there was evidence of the wound going wrong in the first few days after the operation were killed. In reply to further questions, he said experimentation by means of animals was of the greatest use in diagnosing diseases in the interest of public health. An officer of health at a port would use animals, for instance, for the diagnosis of plague or cholera. Those were acute diseases, and at a time in the evolution of the disease when it might be impossible to diagnose it by other means. Asked if it would be possible to throw much light on the physiological processes of digestion and assimilation in men by experimenting on ruminants, the witness replied in the negative. In reply to further questions, he said that in diphtheria it was of the utmost urgency to recognize it at the earliest possible moment. He invariably used the antitoxin in diphtheria. Its efficacy very largely depended upon its early administration. He had not the smallest doubt that the antitoxin saved life and cut short the disease. Proceeding, he said he had no doubt that medicine owed a great deal in the past to animal experimentation, and that it must in the future, if it was to continue to make progress, depend on animal experimentation. It was put to him that it had been suggested that under Certificate B the operation was performed under anaesthetics, but that subsequently exploratory operations were performed without any anaesthetics. To this he replied that was not so. In reply to further questions about the condition of the dogs from which parts of the kidney were extracted, he said he would not say there was pain; but in those animals in which there was the smallest amount of kidney left there was very considerable physical weakness and inability to take food, and therefore he had no doubt there was discomfort. There was never any evidence of local pain, and there was no reason for supposing that there should be. He never heard one of these dogs moan or give any actual signs of acute suffering. Asked about the advantages obtained by inoculation in enabling the physician to form a right diagnosis with regard to, for instance, tuberculosis, he said it tended to indicate the proper treatment, and might be the means of saving life if the wrong treatment were negatived, and the right treatment indicated. Asked if the serum used by Sir Almroth Wright was used curatively, Dr. Rose Bradford replied, "On his patients, I believe so." He had no personal knowledge of any cases in which, for instance, in tuberculosis of the urinary tract, that serum had been used. In reply to Dr. Gaskell, he said he had never found the slightest difficulty in anaesthetizing dogs. He had found them very susceptible to certain anaesthetics, chloroform particularly. One could get the most perfect anaesthesia in dogs. Proceeding, he said he thought the present Act caused a little trouble. Personally, he had never been delayed in the course of any experimental inquiry, but he thought he had known of instances where delay had occurred. He thought experiments on animals should be regulated by an Act. Asked if he had any suggestions to make as to any alterations in the Act, the witness said he thought that certain individuals, at any rate, should have more general powers given them; that, instead of having to apply for certificates for different categories of animals, they might be all covered by one certificate. He would not specify those individuals. He thought that ought to be determined by the people who signed the certificates; they might act as referees with reference to that. They might be defined, perhaps, as teachers and professors of physiology in universities and teachers in medical schools. "Heads of laboratories" would be suitable. He thought there might still be certificates for certain animals, but he would do away with all certificates for persons in the position of head of a laboratory. For men who held less responsible positions he would still require Certificates A, B, C,

and EE, but the certificates might be simplified. In reply to further questions, he said he was in favour of an Act being kept up, because it tended to allay public apprehension. He did not think there was any necessity to set up a standard of humanity for the men engaged in work of that kind, because their object was to relieve humanity.

(To be continued.)

REFUGEES FROM REGGIO.

We are indebted to Mr. P. Heywood Haddfield, M.A., L.R.C.P. and S., Surgeon to R.M.S. *Ophir*, for the following notes on the condition and treatment of the refugees from Reggio received on the Orient Royal Mail liner *Ophir*:

As the *Ophir* was approaching the Straits of Messina on December 31st, 1908, she was signalled to stop at Reggio. Those on board were then in ignorance of the catastrophe, but on arriving at Reggio, just after dark, the Commander was requested to take on board, for transport to Naples, over 800 refugees, including more than 150 seriously injured. Fortunately the passenger season was at its slackest, and it was therefore possible to place a good deal of space at my disposal for the accommodation of the injured. Preparations for the reception of both injured and uninjured were rapidly pushed forward on board. For the latter, in addition to such below-deck accommodation as could be spared, the permanent decked-in promenades were further screened with canvas, and large quantities of fresh and tinned meat, bread and biscuits, and hot drinks were prepared. For the injured greater preparations were necessary. A large dining saloon and a smoke-room were rapidly stripped of all chairs, carpets, and other impedimenta, leaving a large floor and table space available; large supplies of mattresses and bedding were arranged in readiness, and surgical and nursing materials were placed handy on convenient sideboards. So well did the stewards and all concerned work that in a very short time excellent hospitals were extemporized, and before the refugees began to arrive everything was ready for their reception.

First came the uninjured; they were transported from the shore (where the scene of embarkation was illuminated by the searchlight of a warship) in ships' boats towed by the steam pinnaces of the cruisers at anchor. I gathered that all local boats and such small steamers and barges as might have acted as tenders had been destroyed by the tidal waves. Sentries were posted over the accommodation reserved for hospitals to prevent it being rushed by the uninjured. Our sailors assisted to unload the boats and directed the refugees to the decks and the food awaiting them. These people were, for the most part, very poorly clad, and all were wet through and bitterly cold—the night was wet and a piercing wind was blowing. They had been starving and without shelter for three days, but the majority did not make so ravenous an attack on the food as we anticipated; their condition seemed one of complete exhaustion, and their mental faculties were dulled and "mazed"—they just dropped asleep where they lay. Stewards were told off to keep supplies of food and hot drinks going all night, and occasionally I walked through the crowds and picked out such weaklings as required better accommodation.

The injured reached the ship in the same way; they were almost all stretcher cases. The sailors lifted the stretchers from the boats and carried them up the steep accommodation ladder, and then again downstairs to the hospitals. The stretchers were heavy and very long, most awkward to handle in the narrow, twisting alley-ways of a ship. Stewards lifted the patients on to mattresses, which were at once slid along the floor and packed as closely together as possible. The coverings which came with the patients, as well as such mattresses as arrived, were soaking wet, and were at once changed for the warm and dry gear provided by the ship; many patients were stark naked save for a single blanket. Each stretcher, as soon as emptied, was returned ashore, as they could not be spared from the rescue work which was still going on. I had intended to make some slight examination as each sufferer came in, but ignorance of the language made it impossible to do this with sufficient rapidity, and I had to be content with stowing the patients away as quickly as possible. Our accommodation was just at an end as the

last patient was admitted. The *Ophir* at once weighed anchor and proceeded for Naples.

Three Italian Red Cross doctors had come on board, but, exhausted with continuous rescue work, rest was essential to them. I found myself in charge of about 160 very seriously injured and exhausted patients, but was able to congratulate myself on having the valuable aid of Dr. Parish, a passenger on board. It was at once apparent that any attempt at active surgical treatment on board was impossible, for there was no space to move about in and very few of the patients could have been treated. The first aid given ashore had been very efficient, so it was judged best to superintend the comfort and alleviate the symptoms of all, rather than attempt more permanent remedial treatment for a few. With nursing help we were well supplied by the stewards and nurses, who made up for lack of special training by great adaptability and careful obedience to orders. Space was so valuable that it had been impossible to leave alley-ways, and the attendants had to pick their way through and over the patients. Beyond placing the men and women on different sides of the saloon, no separation of the sexes was possible, and the usual decencies of hospitals had to be dispensed with; stewards had frequently to assist the stewardesses in moving women patients. Beef-tea, milk, and coffee were freely dispensed. Coffee seemed to be the drink for which they mostly craved, and considering that the patients were for the most part of the lowest peasant class, I was surprised at their knowledge of and demand for ice. Many cases had to be kept going with stimulants, hot-water bottles, and hypodermic medication; but for full resort to these means they would have died. One woman, moribund on arrival, died during the night; her injuries were, I think, chiefly internal. It was not possible to assuage the universal thirst, for almost all were in a condition of high fever. A great proportion of the men were soldiers; the men bore their sufferings with magnificent fortitude, but most of the women were in a condition of hysteria, and on their side of the room pandemonium raged; the most noisy were the least injured. It was extraordinary to find that much of this disturbance was caused by a belief that the ship was going down; no assurances or argument served to quell it, and comparative quiet—so necessary to the patients—was only obtained by putting some of the most noisy under the influence of morphia.

There was a great similarity in the injuries. In most cases they extended fairly generally over the body. Almost all suffered from fractures and dislocations, and in many cases more than one limb was affected. The fractures were, however, mostly simple, but always accompanied by very severe bruising. Contusions, indeed, were general over all the body; many had black eyes and a great number were suffering from conjunctivitis, set up, no doubt, by the dust clouds of the earthquake. Very severe abrasions were also general, and for the most part were in a septic condition. At first sight many appeared to be severely burned, but I found that this appearance was caused by crusts of earth mixed with blood which, by great pressure, had been so firmly moulded to the surface that separation was nearly impossible. It must be remembered that these people had been rescued from the ruins of houses under which they had been pinned during an exposure of several days. Very many cases were gangrenous. In one man who had a crushed arm and shoulder the gangrene extended over the chest and scapular regions; he had lain three days before being rescued. One woman had been pressed down by a beam the sharp edge of which had cleanly divided the skin along the supraorbital margins from eye to eye, and had fractured and depressed the nasal bones at the frontal articulation; the pressure must then have ceased, for the eyes were uninjured. Several women were expecting to be confined; one case was well on in labour, but after handling gangrene I was anxious to avoid examination; we were able to delay matters till on arrival at Naples the services of a medical man from the Maternity Hospital were procured, and he found that there was just time to remove the case to hospital by a special launch. I did not find that there was evidence of any great hæmorrhage having occurred—probably pressure over the wounds had prevented this; there was no hæmorrhage while on board. It was said that many of the survivors had become mad; we had one such case on board, entirely

uninjured, but I do not know whether the insanity was of recent origin or not. It was a satisfaction to note that during the twenty-four hours spent on the ship the general condition of the patients greatly improved.

It was some considerable time after arrival at Naples before arrangements were complete for disembarkation. Large covered barges were used for this purpose, and the patients were transferred on stretchers by a large staff of evidently overworked and overtired soldiers and sailors. On landing at the Arsenal the injured were conveyed to the hospitals in motor cars and army ambulance wagons.

It is impossible to speak too highly of the work of the crew of this ship. The brunt of it fell on the stewards and stewardesses; the patience and tenderness with which they worked uninterruptedly till the last patient was landed, in a scene calculated to try the nerve of even the experienced, was beyond all praise.

Nova et Vetera.

THE GREAT PLAGUE OF LONDON.

In vol. xiv of *Chambers's Miscellany*, published in the year 1846, there is a masterly tract upon the history of the plague in London in the reign of Charles II, the narrative being made up of an abridgement of Defoe's *Journal of the Plague Year in London*, with a judicious interweaving of some additional particulars gathered from other sources. In this tract are recorded the regulations ordained by the Lord Mayor and magistrates of the City of London for staying and extinguishing the epidemic, and these regulations are worth reproduction now, not only on account of their historical interest, but also because they furnish suggestions which may be of value in the preventive medicine of our own times. Defoe wrote his famous account upwards of fifty years after the events to which it refers. When the plague was raging he could have been but an infant in arms. But he took pains to make his history authentic, by referring to all the parochial and other public records and printed pamphlets by medical men and others relative to the plague year, and also by collecting such anecdotes, narratives and minute particulars as could be obtained from persons who had memories of their personal experiences during the period in question.

In September, 1664, it was announced that plague had appeared in the metropolis. At first little was done to avert the spread of the malady, and it was not until the spring of the year next following that any decided means were put into practice for the suppression of the disease. On May 13th, 1665, an especial Privy Council was held at Whitehall upon the subject of the infection, and a committee of the Lords was appointed to consider the means of checking the progress of the plague. Under the auspices of this committee the Royal College of Physicians drew up a small pamphlet containing directions for the cure of cases of the plague as well as for the prevention of infection. In the beginning of July the Lord Mayor and magistrates of the City published their orders for the sanitary regulation of the part of the metropolis under their control. Pursuant to these, persons were appointed in every parish, with the title of "examiners," who were to be citizens of good repute, and whose office was to last for two months. These examiners were to

be sworn by the aldermen, to inquire and learn from time to time what houses in every parish be visited, and what persons be sick, and of what diseases, as near as they can inform themselves; and, upon doubt in that case, to command restraint of access until it appear what the disease shall prove; and, if they find any person sick of the infection, to give orders to the constable that the house be shut up; and, if the constable shall be found remiss and negligent, to give notice thereof to the alderman of the ward.

In addition to these examiners, there were appointed eleven women-searchers in every parish, such as are of honest reputation, and of the best sort as can be got in this kind; and these to be sworn to make due search and true report, to the utmost of their knowledge, whether the persons whose bodies they are appointed to search do die of the infection, or of what other diseases, as near as they can. No searchers, during the time of visitation, to be permitted to use any public work or employment, or keep a shop or stall, or be employed as a laundress, or in any other common employment whatsoever.

Medical practitioners with especial duties as to the plague were appointed in every parish of the City, and were "sequestered" from any practice other than in cases of the epidemic; with regard to them the orders prescribed:

And forasmuch as the said chirurgians are to be "sequestered from all other cures, and kept only to this disease of the infection," it is ordered that every of the said chirurgians shall have twelve pence a body searched by them, to be paid out of the goods of the party searched, if he be able, or otherwise by the parish.

Besides, there were provided especial nurses or keepers to attend the sick in their homes, and special watchmen were charged with the duty of preventing ingress into or egress from the infected houses. The order as to the watchmen was as follows:

That to every infected house there be appointed two watchmen, one for every day and the other for the night, and that these watchmen have a special care that no person go in or out of such infected houses whereof they have the charge, upon pain of severe punishment. And the said watchmen to do such further offices as their house shall need and require; and if the watchman be sent upon any business, to lock up the house and take the key with him; and the watchman by day to attend until ten o'clock at night, and the watchman by night until six in the morning.

Besides the foregoing, there were certain regulations ordered to be observed by householders, as follows:

Orders concerning infected Houses and Persons Sick of the Plague.—Notice to be given of the sickness. The master of every house, as soon as any one in his house complains of either of *itch*, or purple, or swelling in any part of his body, or falleth otherwise dangerously sick without apparent cause of some other disease, shall give notice thereof to the examiner of health within two hours after the said sign shall appear.

Here was early "notification" made compulsory, and the duty of it placed only upon the "master of every house," and not upon the visiting "chirurgian." Further regulations of the authorities were contained in the following orders:

Sequestration of the Sick.—As soon as any man shall be found by this examiner, chirurgian, or searcher to be sick of the plague, he shall, the same night, be sequestered in the same house; and in case he be so sequestered, then, though they die not, the house wherein he sickened shall be shut up for a month, after the use of the due preservatives taken by the rest.

Airing the Stuff.—For sequestration of the goods and stuff of the infection, their bedding, and apparel, and hangings of chambers must be well aired with fire, and such perfumes as are requisite, within the infected house, before they be taken again to use. This to be done by the appointment of the examiner.

Shutting up of the House.—If any person shall visit any man known to be infected of the plague, or entereth willingly into any known infected house, being not allowed, the house wherein he inhabiteth shall be shut up for certain days by the examiner's direction. None to be removed out of infected houses. That none be removed out of the house where he falleth sick of the infection into any other house in the city except it be to the pest-house, or a tent, or into some such house which the owner of the said house holdeth in his own hands, and occupieth by his own servants, and so a security be given to the said parish whither such remove is made, that the attendance and charge about the said visited persons shall be observed and charged in all the particularities before expressed, without any cost to that parish to which any such remove shall happen to be made; and this remove to be done by night; and it shall be lawful to any person that hath two houses to remove either his sound or his infected people to his spare house at his choice, so as if he send away first his sound, he do not after send thither the sick, nor again into the sick the sound; and that the same which he sendeth be for one week shut up, and secluded from company, for fear of some infection at first not appearing.

Burial of the Dead.—That the burial of the dead by this visitation be at most convenient hours, always before sunrise or after sunset, with the privacy of the churchwardens or constable, and not otherwise, and that no neighbours nor friends be suffered to accompany the corpse to church, or to enter the house visited, upon pain of having his house shut up, or be imprisoned. And that no corpse dying of the infection shall be buried, or remain in any church at the time of common prayer, sermon, or lecture; and that no children be suffered, at the time of burial of any corpse, in any church, churchyard, or burying-place, to come near the corpse, coffin, or grave; and that all graves be at least 5 ft. deep. And further, all public assemblies at other burials are to be foreborne during the continuance of this visitation.

No Infected Stuff to be Uttered. That no clothes, stuff, bedding, or garments, be suffered to be carried or conveyed out of

any infected houses; and that the criers and carriers abroad of bedding or old apparel to be sold or pawned be utterly prohibited and restrained; and no brokers of bedding or old apparel be permitted to make any public show, or hang forth on their stalls, shop-boards, or windows towards any street, lane, common-way, or passage, any old bedding or apparel to be sold, upon pain of imprisonment. And if any broker or other person shall buy any bedding, apparel, or other stuff out of any infected house, within two months after the infection hath been there, his house shall be shut up as infected, and so shall continue shut up twenty days at the least.

Every Visited House to be Marked.—That every house visited be marked with a red cross, of a foot long, in the middle of the door, evident to be seen, and with these usual printed words; that is to say, "Lord have mercy upon us!" to be set close over the same cross, there to continue until lawful opening of the same house.

In illustration of this ordinance it is interesting to find in my copy of *The Diary of Saml Pepys, Esq., F.R.S.*, under the date June 7th, 1665, the following entry:—"The hottest day that ever I felt in my life. This day, much against my will, I did in Drury Lane see two or three houses marked with a red cross upon the doors, and 'Lord have mercy upon us,' writ there."

Every Visited House to be Watched.—That the constables see every house shut up, and to be attended with watchmen, which may keep in, and minister necessities to them at their own charges, if they be able, or at the common charge if they be unable. The shutting up to be for the space of four weeks after all be whole. That precise order be taken that the searchers, chirurgians, keepers, and buriers are not to meet the streets without holding a red rod or wand of three feet in length in their hands, open and evident to be seen; and are not to go into any other house than into their own, or into that whereunto they are directed or sent for, but to forbear or abstain from company, especially when they have been lately used in any such business or attendance.

Inmates.—That where several inmates are in one and the same house, and any person in that house happens to be infected, no other person or family of such house shall be suffered to meet him or themselves without a certificate from the examiners of the health of that parish; or in default thereof, the house whither she or they remove shall be shut up, as in case of visitation.

Hackney Coaches.—That care be taken of hackney coachmen, that they may not, as some of them have been observed to do, after carrying of infected persons to the pest-house and other places, be admitted to common use till their coaches be well aired, and have stood unemployed by the space of five or six days after such service.

These orders were ended by an instruction for the constitution of a permanent committee, with powers to deal with difficulties as they might arise, it being enjoined that the aldermen of the city, with the deputies and common councilmen, should meet together once, twice, thrice, or oftener, weekly, as need might determine, in their respective wards, at some accustomed place, such place being clear from infection of the plague, to consult how the orders of the authorities may be put into execution. The orders quoted above extended only to the city proper, which alone was under the rule of the Lord Mayor and aldermen. Similar precautions, however, were enforced in the extra-civic parts of the capital.

THE German Congress of Internal Medicine will hold its twenty-sixth meeting at Wiesbaden, under the presidency of Dr. Schutze, of Bonn, from April 19th to the 22nd. One subject proposed for discussion is: Mineral metabolism in clinical pathology, to be introduced by Dr. Magnus Levy, in connexion with this subject an address on therapeutic dechlorhydratation will be delivered by Dr. Widal, of Paris. Dr. Henry Head, of London, will deliver an address on sensibility and the testing of sensibility. Among other addresses promised are the following: Dr. A. Bickel (Berlin), the action of mineral substances on the glands of the digestive apparatus; Dr. Kùlbes (Kiel), on the enlargement of the heart in animals; Dr. Lenhartz (Hamburg), on the treatment of gastric ulcer; Dr. Eduard Müller (Breslau), the antiferment of the tryptic pancreas and leucocyte ferment, its occurrence and its uses for diagnostic and therapeutic purposes; and Dr. Plönies (Dresden), the relations of diseases of the stomach to disturbances and diseases of the circulatory apparatus, with special reference to nervous disorders of the heart. All communications relative to the congress should be addressed to Geheimrat Dr. Emil Pfeiffer, Parkstrasse 13, Wiesbaden. There will be an exhibition of preparations, apparatus, and instruments relating to internal medicine in connexion with the congress.

Medical News.

A CONGRESS on therapeutics will be held at Cracow in July of the present year under the presidency of Professor Jaworski of Warsaw.

DRS. PÉDEBIDOU, Labbé, Faisans, Beauvisage, Reymond, and Chaumetens were re-elected members of the French Senate on January 9th.

A SOCIETY of radiology has recently been founded in Paris. Its object is the scientific study of the medical applications of radiations in general.

THE Royal Dental Hospital, Leicester Square, has received a legacy of £200, duty free, under the will of the late Mr. William Joseph Topp, of Rotherhithe.

THE Annual Report for 1908 of the Society for the State Registration of Nurses contains particulars as to the movement in the British Dominions, in the United States, Holland, Germany, Denmark, and Sweden.

DR. ROBERT JONES, Medical Superintendent of the Claybury Asylum, has been appointed Lecturer on Mental Diseases in the medical school of St. Bartholomew's Hospital, in succession to Dr. Claye Shaw, who recently resigned the appointment.

THE Lord President of the Council has appointed Francis E. Fremantle, Esq., M.B., F.R.C.S., M.R.C.P., Medical Officer of Health for the County of Hertford, to be a member of the committee appointed to consider the working of the Midwives Act, 1902.

THE Queen has given a donation of £1,000 to be expended in the purchase of extra-regulation articles which will add to the comfort and convenience of sick soldiers in military hospitals at home stations nursed by Queen Alexandra's Imperial Nursing Service.

AT the meeting of the Royal Microscopical Society on Wednesday next, Lord Avebury will deliver his presidential address on seeds with special reference to British plants, at 20, Hanover Square, at 8 p.m. There will be an exhibition of foraminifera dredged from off the coast of Somaliland.

THE secretaries of the Conolly Norman Memorial Committee desire to remind intending subscribers that the list will be closed on January 31st. Subscriptions will be received by W. R. Dawson, M.D., Farnham House, Finglas, co. Dublin, or by J. R. O'Connell, M.A., LL.D., 34, Kildare Street, Dublin, treasurers.

A NATIONAL ambulance dog society (*Société Nationale de Chien Sanitaire*) has been founded in France. The Minister of War, the Colonial Minister, and the Minister of Agriculture are Honorary Presidents. The President is M. A. Lepel-Cointet; the General Secretary, Dr. Granjux. The object of the society is the breeding and training of dogs to find the wounded in war.

THE General Council of King Edward's Hospital Fund for London held a meeting on January 11th. The proceedings, which were purely formal, consisted of the adoption of the resolutions providing for the work of the Fund during 1909 approved at the meeting in December, and the reception from the Prince of Wales of a communication appointing to the various committees the persons mentioned by him in his concluding remarks on the same occasion.

THE British Association for the Advancement of Science meets this year at Winnipeg from August 25th to September 1st. Professor Sir J. J. Thomson, F.R.S., is the President-elect; the President of the Section of Physiology is Professor Starling, F.R.S.; of the Section of Botany, Lieutenant-Colonel D. Prain, F.R.S., I.M.S., formerly Director of the Botanical Survey of India, and now Director of the Royal Botanic Gardens, Kew; and of Anthropology, Professor J. L. Myres, of Liverpool.

THE British Museum completed on Friday a century and a half of existence, for its doors were opened on January 15th, 1759. It was practically founded by a special Act of Parliament passed in 1753 for the purchase of the collection formed by Sir Hans Sloane, the Harleian MSS., and the Cottonian Library. Sloane, who was born in Ireland, was of Scottish extraction, and took the degree of M.D. in

France in 1684. He made extensive collections during a three years' visit to the West Indies as physician to the Duke of Albemarle. He was afterwards physician to Queen Anne and to George I. and succeeded Newton as President of the Royal Society.

MR. J. G. BUCKLE, B.A., Assistant Secretary of the Dreadnought Hospital, Greenwich, has been selected from a very large number of candidates to be Secretary of University College Hospital in succession to Mr. Newton Nixon. He will take up the duties of his new post on March 29th. Mr. Buckle was educated at Malvern and Magdalen College, Cambridge; he passed into the Colonial Service, and was appointed to Hong Kong, where he held the office of Assistant Colonial Secretary and Secretary to the Executive and Legislative Council. On retiring from the service he became Secretary to the Vice-Chancellor of London University, and subsequently Assistant Secretary at King's College, London. Being attracted to hospital administration he accepted office at the Dreadnought Hospital, Greenwich, where his relationship with the committee and the honorary medical staff has been of the most cordial nature.

THE Belgian Permanent Committee on Human Alimentation, which was founded on the occasion of the International Congress on Food held at Ghent in 1908, held its first meeting at Brussels on December 23rd, 1908, under the presidency of Dr. A. J. J. Vanderveelde of Ghent. Among the objects aimed at by the committee are the organization in Belgium of congresses on food, and the participation of that country in international congresses on the same subject, the study of questions relating to the prevention of fraud, the supervision of the sale and manufacture of food preparations, and the promotion of uniform international methods of analysis. The committee will also investigate the question of human food from the chemical, physiological, technical, commercial, legislative, economic, and social points of view. The committee consists of 50 members representing the scientific as well as the industrial and commercial worlds. There are three vice-presidents, MM. Libotte of Antwerp, Sohier of Liège, and Professor van Laer of Brussels; Dr. Schoofs of Liège is General Secretary.

In a letter addressed to Sir Alfred Jones, Chairman of the Liverpool School of Tropical Medicine, Mr. R. Newstead, who is engaged in studying destructive insect life in Jamaica, says that the work of the expedition is progressing most favourably. Mr. Wortley, Lecturer in the Department of Agriculture, was appointed officially by the Governor to assist in the investigations. Mr. Newstead says he has already inspected several large cattle-pens in the West, and has made arrangements to see other estates in various parts of the island. He has also sent out 150 tubes to other localities, with the request that ticks be forwarded from various animals. Further, he has issued circulars asking for information regarding cattle ticks. He has a number of eggs from the various ticks, and as soon as the larvae hatch he intends to put them on material which the Government has placed at his disposal. He hopes to make a series of control experiments and test a few of the remedies which are used by the planters. Dr. Frout, C.M.G., and Dr. Hanley, C.M.G., the medical officers attached to the expedition, are pursuing their investigations into the various diseases indigenous to the island.

TRYPANOSOMES are very common in the blood of horses and other animals along the East Coast of Africa generally, so that it is not surprising to learn that they have also been found in Zanzibar. Dr. Alexander Edington, while passing through there, had his attention called to a horse which showed well-marked swelling of the abdomen and sheath, and on examining its blood trypanosomes were found. Inoculations into another horse, an ox, a donkey, and other animals were positive as regards the former two. The length of the parasite as seen in the blood of horses is 15 μ , on an average, and the breadth 1 μ ; in size it resembles the *T. dimorphum*, but M. Mesnil, to whom specimens were shown, considers it to be different both from this and *T. congolense*, a somewhat similar parasite. Koch and others have also described trypanosomes in horses from Togoland, and it may be that this parasite is similar to some of these. The whole subject of the classification of trypanosomes in horses and other animals in Africa is in a very unsatisfactory condition, and it is to be hoped that no new name will be attached to this one unless it can be shown that it has real claims to a specific entity. Dr. Edington's paper was read before the Royal Society on November 12th, 1908.

British Medical Journal.

SATURDAY, JANUARY 16TH, 1909.

THE INEBRIATES ACTS.

THE Report of the Departmental Committee appointed by the Home Secretary to inquire into the operation of the law relating to inebriates and to their detention in reformatories and retreats is an unusually long document, but of so much general interest and of such importance to the medical profession that its essential points are reproduced in the SUPPLEMENT this week.

The original intention of the Home Secretary was to reconstitute the Committee after it had reported on the Inebriates Acts, and to entrust it with the task of inquiring into the methods of treating drunkenness by means of drugs, thus fulfilling a promise made some time ago to a deputation of parties interested that waited upon him on the subject. The Committee, however, asked for this reference at a comparatively early stage of its labours, and dealt with it without being reconstituted, unless the absence of Dr. Branthwaite from its deliberations on this subject is to be considered a reconstitution. The promise ought never to have been given. It is not the business of the State to investigate the merits of secret and proprietary "cures" exploited for private profit. The members of the Committee evidently took this view, and their report appears to show that they resented the intention to impose such a task upon them. The Departmental Committee, in agreement with the British Medical Association, which in 1906 published a report on the subject (also reproduced in the SUPPLEMENT this week), soon arrived at the conclusion that further powers and facilities for the detention of inebriates are urgently needed, but it was confronted by the possibility that some "cure" might be alleged to be a practicable alternative to detention; so, although the members of the Committee thought it inherently improbable that any treatment by drugs could be enforced by Act of Parliament, they applied for the issue to them of the second reference in order to determine this point.

Their reasons for so thinking were: (1) That it would be impracticable to set forth in an Act of Parliament the various modifications of any specific treatment that must be required by the varying needs of the individual cases; (2) that the opposition to compulsory vaccination showed that the attempt to enforce medical treatment by Act of Parliament produced friction, discontent, and agitation; (3) that it was unjustifiable to tie the hands of medical men to one mode of treatment, and (4) that it would be impracticable, for reasons given, to carry out any specific treatment even if it could be embodied in a statute. The notion of an offender being bound over to come up for treatment so many times a day is, indeed, sufficiently preposterous. This portion of the report ends by deprecating any further public inquiry into the subject.

The section of the report which contains general observations on the nature of inebriety by the medical members of the Committee is, as far as we know, a unique feature in a Government report, and is worthy of imitation, since it lays a foundation on which the whole of the rest of the report is built. It is reproduced in full in the SUPPLEMENT, and is worthy of careful perusal, as it treats the problem of inebriety in a thoroughly scientific spirit. Its leading feature is the repudiation of the dictum that inebriety is a disease; "it is," the report says, "erroneous and disastrous to inculcate the doctrine that inebriety, once established, is to be accepted with fatalistic resignation, and that the inebriate is not to be encouraged to make any effort to mend his ways."

This Committee is the third appointed by Government which has reported that there is urgent necessity for legislation to enable compulsory control to be exercised over the "private inebriate" who devastates his home without committing any public offence. This, it will be seen, was a point made in the British Medical Association's report, but the recommendation now made differs from those of previous Government committees in offering a thought-out scheme of procedure, not merely recommending "proper safeguards," but indicating precisely the safeguards that should be enforced. The first novelty is the proposal to institute a statutory pledge, to be taken voluntarily, but breach of which is to bring liability to the imposition of compulsory measures. The next step also is voluntary. An inebriate may apply to be placed under guardianship, so that, without going to a Retreat, he may be restrained from obtaining intoxicants. If the voluntary guardianship is ineffectual, or if voluntary guardianship is declined by the inebriate, he may be placed compulsorily under guardianship, or sent to a Retreat. The scheme is elaborate and well considered, and it is to be hoped that the Legislature will at last yield to the importunity of official committees, supported by the unanimous voice of the medical profession, and embody it in an Act of Parliament.

The alterations recommended in the Inebriates Act, 1898, are of the most drastic description. More than a million and three-quarters cases of drunkenness have been heard by courts of first instance since this Act came into force, and yet only some 2,600 persons have been dealt with under this Act. The Committee might have added that there are at the present time more than a hundred women in Holloway Gaol qualified to be dealt with, but who cannot be dealt with because the London County Council refuses to find its share of the expense of maintenance. The Committee has investigated very thoroughly the causes of this failure of the Act, and enumerates them under six headings. They find that while some magistrates overlook the Act, others are unwilling, for various reasons, to put it in force. Among these reasons is a frank disbelief in the efficacy of detention as a reformatory agent. The Committee, while pointing out that as only the very worst cases have hitherto been committed, reform was scarcely to be expected, expresses the opinion that reform is not the sole motive of detention, and argues that it is right and just that the inebriate should be detained, even if he be irreformable. He should be detained because he is a noxious element in society, and society has a right to protect itself against his depredations.

It is surprising how great a stumbling-block has been constituted by the definition of "habitual drunkard"

given in the Act of 1879. In several courts the Act has become a dead letter for this reason alone: the magistrates, although they desire to commit drunkards under the Act, find themselves unable to do so because they cannot satisfy themselves that the quasi-inebriate can be included in the definition. The Committee enumerates no fewer than nine defects that have been discovered in practice in the definition, and it has framed a new definition which is held to be free from defect. It presents, however, all the marks of a compromise. The general skeleton is unexceptionable as far as we are able to discern, but how a Committee that has done excellent work in other directions should imagine that an Act of Parliament could contain in a definition such a phrase as "ordinary proper conduct" we are unable to understand.

The next matter in the 1898 Act that is overhauled is the provision which prevents an inebriate being sent to a Reformatory until he has been four times convicted in one year. The Committee declares that an inebriate may have been convicted three or more times without the magistrate before whom he is brought for the fourth time knowing of the previous convictions; that many inebriates, both reformable and irreformable, are able to escape the three convictions; that irreformable inebriates of the worst kind, just liberated from the Reformatories, and plunging into drunkenness again, cannot be recommitted to a Reformatory until they have been four more times convicted; and that ordinary Bank Holiday drunkards, who are not inebriates at all, may nevertheless be convicted four times in a year.

The Committee advises the abolition of the three years' sentence, and propose instead of it an elaborate system of graduated sentences, beginning with discharge on probation, and increasing to detention for three years. In every case, the sentence is for "not exceeding" so long, the implication being that the period of actual detention is at the discretion of the authorities of the Reformatory in which the person is being treated. In no case is an inebriate to be liberated except on probation, and failure on probation is to be followed by immediate recommitment to a Reformatory for a longer period.

The Report terminates with a chapter on finance, in which the extravagance and waste of certain local authorities is condemned, and a strong case made out for the assumption of the whole care of inebriates by the State alone, as cheaper and more efficient. The limits of expenditure laid down are £150 a bed for accommodation, and 11s. 4d. a week for maintenance, limits which are greatly exceeded by several local authorities.

Amid the isolated recommendations scattered throughout the Report is one that persons who, by delirium tremens, make themselves a charge upon the rates, should be *prima facie* considered inebriates, and liable to be proceeded against as such at the instance of the Guardians to whom they have made themselves chargeable; and another, that the work done by the inmates of Reformatories is insufficient and unremunerative, and should be reorganized.

It will be seen that the Report is very elaborate and detailed in character; it suggests several new principles and many novelties of detail in dealing both with those inebriates who offend against the law, and those who do not. It has evidently been a work of great labour, and has had much thought expended on it.

THE ETIOLOGY OF TUBERCULOSIS.

THERE is at present much difference of opinion as to the manner in which the tubercle bacillus gains entrance to the body. The old theory is that the bacilli are inhaled. The advocates of this view are divided into two camps. Cornet and his disciples think that the bacilli are derived from the sputum, which when dry becomes dust and is inhaled as such. Flügge and his pupils hold that the chief source of inhaled bacilli is the spray which issues from the mouths of consumptives whilst speaking and coughing. A theory which has recently gained many adherents, owing to its advocacy by Calmette and his supporters, amongst whom are to be mentioned Whitla and Symmers of Belfast, is that the bacilli gain access to the lungs by way of the alimentary canal; that the mechanism for preventing the access of bacilli to the lungs is so perfect that bacilli can get there only by the intestine, the mesenteric glands, and the thoracic duct. This doctrine has been extended to embrace the origin of anthracosis and other dust diseases of the lungs. It has met with strong opposition from the Breslau Institute of Hygiene. A series of researches from this institute under the direction of Flügge has recently appeared in the *Zeitschrift für Hygiene*; abstracts of these were published in the *EPITOME* last week, No. 23, pp. 7 and 8. The experiments and arguments adduced are so numerous that it is difficult to do justice to them in a short summary. It is assumed that all the modes of infection have been shown to be possible, so that in order to estimate their importance it is necessary to gauge their probability by careful quantitative experiments. It is asserted that alimentary infection in the guinea-pig is possible only when the quantity of bacilli ingested is over 300,000 times the quantity sufficient to cause an infection when inhaled. In the case of the goat and the rabbit the same relations were found to hold, but the experiments were not sufficiently numerous to give such definite figures. The statement that the rabbit is much less susceptible to human bacilli than to bovine is confirmed by the Breslau experimenters.

Another research showed that the spores of harmless organisms could be demonstrated, both by microscopical and biological methods, in the pulmonary tissues within three hours after their inhalation. Feeding experiments, although carried on for a long time with large quantities, never resulted in the spores being found in the lungs. Inhalation of tubercle bacilli, in doses harmless when taken into the alimentary canal, resulted in the bacilli being demonstrated in the alveolar septa and other parts of the lungs within one hour. It was further shown that with small doses the bacilli could not be found in the bronchial lymph glands until after three days. Evidence was found also to support the conclusion that the alimentary canal is almost impermeable to tubercle bacilli when they are taken with the food under natural conditions. The predominance of pulmonary lesions after either alimentary or intravenous infection, it was concluded, was due not to mechanical factors—retention by the lungs as by a filter—but to some special predisposition on their part to tuberculosis. In regard to milk, quantitative experiments afforded evidence that in tuberculous herd milk (not the milk of a single cow), when drunk at the rate of a litre a day, the bacilli are not likely to be so plentiful as to be dangerous. This is supported by statistics which are held to show that in *Persucht* districts there is no increased incidence

of tuberculosis, and that there is as much tuberculosis of all kinds in countries where there is no consumption of tuberculous milk. Bovine infection, it is concluded, is uncommon even in children's surgical tuberculosis. The Breslau experimenters emphasize the view that pulmonary tubercle, the great scourge of humanity, is due to the human type of bacillus. The position taken up is that milk inspection is not to be condemned on these results, but great benefits from it are not probable and must not blind us to other sources of infection. The attempt to prove the improbability of finger infection is not so satisfactory, for bacilli were found on the fingers of 10 per cent. of the children. As these results are from one examination of each child, it is thought possible that every ten days each child would have contaminated its fingers.

It is no new idea to regard tuberculosis as a disease of childhood, but von Behring may claim to have been the first to produce scientific evidence in its favour. Naegeli long ago asserted that nearly every adult inhabitant of Europe harbours a tuberculous focus, and Dr. Franz Hamburger, of Vienna, who has tested a large number of apparently healthy children with tuberculin, by cutaneous or subcutaneous application, states¹ that at the age of puberty over 90 per cent. give a positive reaction. *Post-mortem* examination of individuals at this age revealed that 75 per cent. were definitely tuberculous. He argues that nearly every individual, except a few fortunate residents in rural districts, acquires tuberculosis before the age of 14 years. The clinical signs of the disease may not develop for the bacilli may enter the system without producing any characteristic changes, and may lie latent in a gland or other organ until some accident determines their active growth. It may be that, as Bartels found in animals, the bacilli gaining entrance without producing any local change, lie dormant or nearly so in the glands, producing in them general swelling and hyperplasia, but no formation of tubercles. On the other hand, the bacilli may produce a primary characteristic lesion at the site of entry, with the formation of tubercles and caseation in the related lymphatic glands. In attempting to follow the process beyond this point, Hamburger relies on *post-mortem* as well as on clinical evidence. The tuberculous process may remain localized in the seat of infection and in the lymphatic glands, and is then usually not diagnosable except by the use of tuberculin. The infection may then become inactive, or it may develop farther in one of several ways. The caseating masses may open into a vessel, and a large number of bacilli, being thrown suddenly into the circulation, acute miliary tuberculosis is produced. In other cases the bacilli, owing to causes still unknown, give rise to tuberculous meningitis. If, again, the number of bacilli which escape is small, and if the majority are arrested in one special tissue, localized tuberculosis of bones or glands is produced, or the lymphatic glands may become generally affected, producing general lymphatic gland tuberculosis, and from the bronchial glands the infection may spread to the lungs. Hamburger states that in the large majority of children the infection remains in abeyance for years or permanently, but he believes that the evidence he has accumulated is sufficient to establish the proposition that tuberculosis in adults is usually a recurrence of the disease acquired in childhood, and goes on to suggest that adult phthisis is a tuberculous

process grafted on an already tuberculous organism; Orth is said to have arrived at a similar conclusion, basing his opinion on the results of experiments on animals.

The conclusions of the Breslau school, to which we have referred in the earlier part of this article, will doubtless be subjected to keen criticism. Accurate quantitative work in bacteriology is notoriously difficult. It seems probable, however, that the great difference between the alimentary and the inhalation infective dose is too striking to be due to error or bias. This one fact, if fact it be, gives importance to the work.

THE CHARTER AND THE REFERENDUM.

IN consequence of a point of order raised at the meeting of the Metropolitan Counties Branch on December 30th, the full report of which meeting has not yet been received for publication, the Organization Committee resolved to take legal opinion on the points whether (1) a Branch (or Division) which circularizes Members with the view of ascertaining the individual feeling of Members, and either alone or in combination with other Branches proposes to petition the Privy Council in opposition to the grant of the Charter in the form in which it is presented is acting *ultra vires*; (2) if so, what means are open to be taken to stop such action; and (3) whether expenditure incurred by Branches (or Divisions) in such action is legitimately chargeable to Branch (or Division) funds. The case submitted to counsel and counsel's opinion are published in the SUPPLEMENT for this week, page 21. The case and the opinion should be read in their entirety, but we observe that Mr. Colquhoun Dill is of opinion that a Branch (or a Division) cannot legitimately act in opposition to a decision of the Representative Meeting and cannot apply Branch (or Division) funds in promoting a petition to the Privy Council or obtaining the opinion of the Members of the Branch (or Division) as to whether such a petition should be presented. We, of course, make no comment upon the point at issue, but desire merely to draw the attention of members to the special report of the Organization Committee embodying Mr. Colquhoun Dill's opinion, which will no doubt be submitted to the Council of the Association at its meeting on January 27th.

THE FUNCTION OF SCIENCE IN EDUCATION.

THE annual meeting of the Association of Public School Science Masters was held on January 12th, Sir Clifford Allbutt, the President, being in the chair. In his presidential address the Regius Professor of Physic in the University of Cambridge discussed, with the breadth of outlook and mingled grace and lucidity of expression which distinguish his utterances, the place of science in school education. He said that the field of natural science was for most boys the best foundation of scientific training. The scientific method penetrated into all studies of the modern school, as it penetrated into all life. The humanist winced to see the flower of literature stiffened into a diagram; not only did he deny creative power to science, but he suspected it of corrosive properties, and so was tempted to denounce all compact with it. Imagination was a precious faculty, for which the Olympian schoolmaster professed himself peculiarly jealous. Yet to literature in the sense of food for the imagination very few boys attained. Sir Clifford Allbutt said that our eyes should be open to that besetting sin of the schoolmaster and its devastating consequences whereby the ingenuous and ardent curiosity and recep-

¹ *Munch. med. Woch.*, December 29th, 1908.

tivity of the boy were quenched and deadened so that too often in ideas he remained impoverished for the rest of his life. There was a tendency in school, in spite of science, to forget that there were boys and boys. To most boys natural history and mechanics would prove more congenial than chemistry. In the upper forms there should be a more extensive differentiation, according to the bents, and possibly even the vocations, of the pupils. Sir Clifford Allbutt added that Cambridge had recently opened the First M.B. Examination to candidates on admission. He concluded by saying that his speech would be in vain if he had not half persuaded even the head masters that no boy's education was broad and symmetrical which had contained less science than was required, say, for that examination. In reply to a vote of thanks passed for his address, Sir Clifford Allbutt said it was a profound error to have modern and classical sides in a school. The classics and science ought to be taken together. While agreeing with Sir Clifford Allbutt, as a general proposition, that science should find a place in school education, we think that the foundation of teaching should still be what, for want of a better term, we may call humanistic. Boys who have had no opportunity of acquiring any knowledge of science at school can make up the deficiency later, but strict accuracy in the understanding and the use of words, the ready and correct grasp of a writer's meaning, the intuitive perception of a fallacy, can seldom be acquired otherwise than by means of a classical training, except by men of genius who are a law unto themselves. We make bold to say that research would not so often wander into devious tracks which lead nowhere if all scientific investigators had been thoroughly drilled to appreciate the significance of words, and had mastered the rules of reasoning. It is true, of course, that a knowledge of grammar will not of itself enable a man to speak properly, any more than a knowledge of logic will necessarily make a sound thinker. For illustrations of these statements we may point to the lack of sense of style shown in the writings of many scholars, and the bad reasoning of many of those who have been nurtured in the logic of the schools. Nevertheless the fact remains that men who have been through the humanistic training, though they may have forgotten the small Latin and less Greek they learnt at school, are, as a rule, better able, in the words of the poet, to see life steadily and see it whole, to appreciate evidence and to put their ideas into words that accurately convey their meaning, than those who have got their intellectual nourishment at the somewhat dry breast of Science. There is a scientific pedantry which is far more narrowing to the mind and withering to imagination than that of those who spend themselves in mastering the mysteries of the "enclitic *De*." And without imagination properly used no great advance in science has ever been made.

SPIRITUAL HEALING.

In a paragraph on the spiritual healing movement which appeared in the *BRITISH MEDICAL JOURNAL* of November 21st, 1908, we said that, while we could understand why the clergy should seek to find fresh woods and pastures new for their ministrations in the dark places of nervous disease, we were surprised that one of the authors of *Religion and Medicine*, the Rev. Elwood Worcester, D.D., should be able to say that before beginning the work they had secured the sanction of the leading neurologists of New York. In reference to this we have received a letter from Dr. Waller L. Burrage of Boston, with a copy of the *Boston Sunday Herald* of December 27th, which puts the matter in a different light. As the result of inquiry among eminent physicians, that journal states that

"the consensus of opinion in medical circles is that the 'Emmanuel Movement' has belted with its promoters 'and is running riot; is doing much harm.'" Dr. J. J. Putnam, Professor of Nervous Diseases at Harvard, denied that he approved of the movement, and protested against the use of his name in any manner in connexion with it. He considered the whole affair an injury to the progress of scientific medicine, especially to neurology. Two years ago the Rev. Dr. Worcester had spoken to him about the use of suggestion in certain forms of morbid nervous conditions, and Dr. Putnam then agreed that many cases of depression and moral instability could be benefited by suggestion along proper lines. Dr. Worcester, he added, had given him to understand that his idea was to select those of his parishioners who needed suggestive help, and if there were no real physical disturbances, to lead them along the line of self-control by suggestion. Dr. Putnam further agreed that many of these unfortunate needed assistance in the way of getting some occupation that would stop their introspection and worry. This, he said, was the extent of his advocacy of the practice of psycho-therapeutics by clergymen or any other body of untrained men. He added that he was sure this was the way in which some of his colleagues had been misunderstood "in the deplorable 'matter.'" Dr. Putnam complained that, notwithstanding an emphatic repudiation addressed to the Rev. Dr. Worcester, his name continued to be associated with the movement. He went on to say that the claims of the promoters of the movement were misleading, if not something else. It was a veritable epidemic which should be limited and controlled. "The crowd of untrained and unfitted clergymen 'who at once jump into the rôle of medical men 'and preach and practise what they call psycho-therapeutics is going to do great harm, is an injury 'to the public welfare.'" Dr. Philip Coombs Knapp, Clinical Instructor in Nervous Diseases at Harvard, said his objection to the Emmanuel movement was that it was bringing a horde of unfitted clergy to believe that they could by a few weeks' reading treat diseases of the nervous system. He added that "already there are prominent signs 'that the fad has been used for commercial purposes.'" Dr. William Lee Howard said that "the 'trouble with all these religious sects that claim 'to cure diseases is that they mix up metaphysics 'with physiology, sin with pathology.'" Dr. J. J. Thomas, Assistant Professor of Neurology at Tufts Medical College, said, in regard to the movement: "We do not endorse any such work. . . . Disturbances 'of the nervous system, and the symptoms of these 'disturbances, which are shown in so many various 'ways—physical forms—can only be understood by 'those whose training has been thorough in general 'medicine and who have then specialized in the 'anatomy and physiology of the nervous system.'" Dr. Thomas further referred to the danger to which most forms of mental healing sooner or later succumb, that of attempting the cure of cases unsuited for the psychical method, adding that from published reports in popular magazines the Emmanuel movement had evidently reached this point. Dr. George Waterman, Assistant Professor of Nervous Diseases at Harvard, said he was tired of hearing about the movement, which he did not approve of in any shape or form. Dr. Frank C. Richardson, Clinical Professor of Neurology in Boston University, expressed his hearty agreement with the opinions which we have here summarized. It is plain, therefore, that the statement that the Emmanuel movement has the sanction of "the leading neurologists in New England" is inaccurate. From the

New York Medical Journal we learn that Drs. Joseph Collins and J. Leonard Corning have expressed disapproval of the movement. On the other hand, Dr. Allen Starr looks upon it more favourably, though with reservations which are virtually in harmony with the view expressed in the BRITISH MEDICAL JOURNAL—that is to say, that the medical profession is ready to welcome the co-operation of the clergy in dealing with certain kinds of nervous disease so long as they do not step outside their proper sphere of purely spiritual ministration.

AN ALPINE CLIMATE IN EARLY TUBERCULOSIS.

THE tendency that shows itself throughout the history of medicine to work a sound idea to a point where it becomes useless or even dangerous has in recent years been shown in the excess of zeal with which the open-air treatment has been applied. It has been said that climate counts for nothing, and that our own happy island, with its capricious changes of climatic mood, is as good as that of the more favoured places whither pilgrims flock in search of health. The sentiment is patriotic, but its results, when translated into action, are not always satisfactory. Patients in the early stages of consumption are encouraged to go through the open-air ritual even amid the fogs varied by rain with all the rapid changes of temperature of a London winter, which oblige even the healthy each morning to think of the possibilities of the coming day, and make the problem wherewith they shall be clothed one that the most experienced must give up in despair. Where, then, are such patients to go? To this question Dr. Ewart supplies an answer in a paper published in this week's issue. He may seem at first sight to harp on a familiar string, for the virtues of Davos are admitted by all. They may appear to be summed up in the words of Justice Shallow, "Marry, good air." This may doubtless be said of many other places, but for most of those threatened with consumption the climate of the Alps possesses special advantages. It is a significant fact that even in the sanitary darkness of the Middle Ages consumption was not endemic in Davos. It may, however, be said that for the bulk of people over whom broods the shadow of the "white plague" a stay in Davos is a counsel of perfection. Thanks to the efforts of a number of enlightened men, of whom Dr. Ewart himself is one of the most prominent, this difficulty will shortly be in some measure removed. A national sanatorium at Davos, which bears Her Majesty's name, is now nearing completion, but funds are still needed before it can be made ready for occupation. Dr. Ewart does not plead for money, but we venture to do so on his behalf. It will be a reproach to this country if the usefulness of an institution like the Queen Alexandra Sanatorium is suffered to be crippled for the want of money. We are sure this will not be the case. Money, however, is not everything; it must be applied in the right way if the sanatorium is to perform to the fullest measure of efficiency the function for which it is intended. It is here that Dr. Ewart's advice, founded on his large experience, is particularly valuable. He urges that in order to secure the greatest possible advantage patients should not be kept here, even under the favourable conditions of one of our home sanatoriums, but should be sent in the first instance to the Alps. The benefit thus gained will be maintained and increased by a further course of properly-directed treatment at home. His thesis, in short, is that the best hope of effecting a cure in early tuberculosis is a systematic combination of home with Alpine treatment. But he lays special stress on the importance of the patient being sent to Davos first. Of

course, the special features of each case must be taken into account. There are cases in which the altitude treatment is unsuitable; these are fairly and fully set forth by Dr. Ewart. In any case, patients should not be sent to Davos as a last resource. In pulmonary tuberculosis the fundamental principle of treatment is expressed in the words of the Latin poet, *venienti occurrere morbo*; to advise an obviously doomed patient to go to Davos or anywhere else is to invert the maxim and send the sufferer to seek his death amid surroundings that must make the parting from life more bitter. We commend Dr. Ewart's paper to the serious attention of our readers.

THE HEREFORD COUNTY MEDICAL OFFICERSHIP.

THE earlier history of the action of the Herefordshire county authorities with regard to the appointment of a medical officer for the county has already been related in the JOURNAL.¹ It will be remembered that Dr. Herbert Jones, who held the office of medical officer of health for certain combined sanitary districts in the county, was, at the end of August last, appointed county medical officer of health and school medical officer at a salary of £500 a year. After his election an agreement was placed before him the terms of which differed from those upon which he understood he was appointed, and from any agreements of which we have ever heard of a like kind. The medical officer was asked to contract to pay for any qualified medical assistance he might need in carrying out the duty of the medical inspection of children; to pay office expenses incurred by him as medical officer to the county, with the exception of the cost of certain forms, books, and apparatus, and to pay his travelling expenses. Dr. Jones very properly declined the appointment on these terms, and resumed the duties of medical officer of health to the combined sanitary districts—the appointment he had previously held. Under these circumstances there can be no doubt that the regular and proper course for the Herefordshire County Council or its Public Health Committee would have been to advertise the appointment again. Instead of taking this course the clerk to the County Council wrote to each candidate who had responded to the first advertisement, asking him whether he would be willing that his application should be considered to be still before the committee, but did not in so doing intimate the reason why Dr. Jones has declined to take up the appointment. The facts coming to the knowledge of the Public Health Committee of the British Medical Association, the Medical Secretary was instructed to communicate with all the candidates, informing them of the terms in the agreement which had led Dr. Jones to decline the appointment. Two of the candidates, Dr. Lindsay and Dr. Bygott, decided to apply again upon the condition that the terms of the appointment should be such as the Hereford Division of the Association could approve, having in the meanwhile ascertained it was not the intention of the Public Health Committee of the County Council that the medical officer should be called upon to pay office expenses. A new agreement was drawn up by the clerk to the Herefordshire County Council, and the Public Health Committee of the British Medical Association, having taken legal advice, warned Drs. Lindsay and Bygott, the selected candidates, not to sign it, as it still contained clauses under which they would be liable for various expenses. This advice was taken by these two gentlemen, and as a consequence this second agreement was withdrawn and a third substituted which set out clearly that the only expenses to fall on the medical officer to the County Council were

¹ BRITISH MEDICAL JOURNAL, 1908, vol. ii, pp. 1204, 1308.

travelling expenses. Dr. Bygott, having obtained another appointment, withdrew his candidature; and Dr. Lindsay, being the only selected candidate remaining, might no doubt have secured the appointment for himself, but very chivalrously allowed the particulars of the altered agreement to be made known to all the original candidates and took his chance with them. The result was that the County Council preferred to appoint Dr. Gold, who has accepted the appointment upon the terms of the agreement settled with the advice of the British Medical Association. We sympathize both with Dr. Herbert Jones and with Dr. Lindsay, who seem to have had rather hard measure dealt out to them; but they will have the satisfaction of feeling that they have contributed to prevent the institution of a precedent which could not but have had most disastrous consequences to the public health services.

PRIVATE SANATORIUMS FOR CONSUMPTION AND CANCER.

THE danger to the public of unqualified medical practice is becoming more and more manifest, and is well illustrated in the report of the inquest on a patient who died in a private home conducted by a Mr. J. H. D. Jenkinson at Handsworth, near Birmingham, for the treatment of cases of consumption and cancer. Mr. Jenkinson said he was a chemist and druggist, but had no medical diploma. Before he opened the home he had been in business as a manufacturer of poultry, pigeon, and dog medicines. He received principally consumptive cases, but had had three cases of cancer. According to the sister of the deceased, who had also been in the home, they paid 10s. a week each for board, lodging, and treatment. There is certainly no complaint to be made on the score of expense, and it is astonishing to hear that cases can be properly boarded and lodged for so small an amount, as, according to Bardswell's table, the cost of the diets in working-class sanatoriums, where presumably purchasing was done at contract rates, varied from 13½d. to 22d. a day, so that food alone should cost at least 2s. a week. Mr. Jenkinson was obviously unable to provide medical attendance for this small remuneration, and seems to have contented himself by giving the patient what he called a "high-class tonic," and only sent for the doctor when the patient was dying; hence the inquest. We shall watch with interest the proceedings of Mr. Jenkinson and the home which he conducts with such remarkable economy. The position of the doctor who was called to the patient when *in extremis* was somewhat difficult; if he had given a certificate he might have been considered to be covering Mr. Jenkinson and assisting him in carrying on his unqualified practice. He therefore quite properly consulted the coroner, who in the public interest held an inquest, which has had the desirable result of giving due publicity to the matter. The principle of free trade in institutions of this kind can only lead to scandals. It is evident that they ought to be subjected to some kind of supervision, which might be placed in the hands of local authorities, town or county councils, as we have no wish to see another central body created in London like the Lunacy Board.

MEDICAL THOUGHT IN AUSTRALIA.

ON the proceedings of the recent Australasian Medical Congress a not inappropriate comment would be *coelum non animus mutant*, even though many of those who took part in it are lifelong inhabitants of that part of the globe. To any one, in short, who has followed the account, which is concluded in this issue (page 160), it must be abundantly

clear that the minds of medical men in Australasia and in this country are pursuing identical lines of thought. That this should be the case in scientific matters is not remarkable, but it is interesting that the professional and medico-political subjects discussed at this congress were in so many instances the same as those which received attention at the annual meeting of the British Medical Association at Sheffield. Clearly the conditions with which the medical profession, individually and as a whole, has to deal at the antipodes are closely similar to those in these islands. The president, Professor Allen, devoted much of his address to a consideration of means of lessening maternal mortality in childbirth and of providing increased protection for infants. Much, he noted, had been done for children in late years, but more remained, especially in regard to the prevention of ophthalmia neonatorum. Similarly the address in medicine dwelt upon the marked increase in functional disorders of the nervous system. In view of a suggestion recently put forward here that the physician of to-day ought to undertake some of the procedures hitherto regarded as within the province of surgeons, it is interesting to note that at this congress gynaecologists were urged to regard the whole abdomen and not merely the pelvis as their preserve. Consolation may be derived by those depressed at the conditions among school children in Great Britain from a fact revealed by Miss Gertrude Hally in her interesting account of medical inspection as conducted in Hobart. Out of over 11,000 children examined between certain dates, as many as 38.6 per cent. were found defective to such a degree as to be probably unable to receive full benefit from the education provided in the ordinary schools. On the other hand, a feeling of envy may well be evoked in the minds of many medical officers of health by the statement that it is now in the power of any New Zealand municipality to say, "No one shall sell milk in our borough unless it 'has passed through our conduit, and has been certified as pure and wholesome by our Health Department.'" Hospital abuse also came in for very full consideration, and was the subject of several resolutions. One of these was to the effect that no payment whatever ought to be accepted from patients admitted to institutions maintained either by charitable subscriptions or by Government funds, and that except in case of accidents and emergencies all patients should be required to sign a statement of inability to pay for medical treatment, and should usually be expected to furnish themselves with a recommendation from their ordinary medical attendants. Similar views have frequently been urged in this country. A further resolution dealt with hospitals for patients who can afford to pay. It was somewhat obscurely worded, but the mover clearly explained what it meant and what the object in view was. He desired to see hospitals nationalized and new institutions provided to which only persons able to pay would be admitted. The charges of these institutions should everywhere be the same, and they should possess neither out-patient departments nor a medical staff; each patient should be left free to choose his own medical attendant, and to agree with him as to the fees to be paid for professional treatment. The next congress is to be held in 1911 at Sydney, and Dr. Pockley, a distinguished ophthalmologist in that city, is to be its president.

THE HEALTH OF LONDON.

THE annual report for 1907 of the Medical Officer of Health for the County of London has just been issued with a short preliminary note by the Public Health Committee. The most satisfactory fact which Sir

Shirley Murphy has to record is perhaps that the death-rate, which stood at 15.1 in 1905 and 1906, fell still further in 1907 to 14.6, which is a lower rate than was recorded in any English town having a population of over 200,000, with the exception of Bristol (13.2) and Leicester (12.7). An unsatisfactory fact is that the birth-rate, like the death-rate, is the lowest on record for London. The marriage-rate was also lower than for many years. Two diagrams on the same page show in a striking way the relation of both birth and marriage rates to the means for the years 1851-1907; there is a general correspondence, but the fall in the births began later (1888), and has been more rapid and continuous than that in marriages, which began in 1878, and has shown marked fluctuations. The statistics with regard to phthisis show that the gradual decrease in mortality noted in previous years has continued, but the most interesting point in this section of the report is contained in a table showing phthisis death-rates in relation to overcrowding. In those districts in which the percentage of overcrowding is lowest (7.5 per cent.) the corrected death-rate per 1,000 persons living was 1.078; in those in which overcrowding is worst (27.5 per cent.) the corrected death-rate was 2.118. It is instructive to compare these figures with those in a similar table for cancer, where no correspondence between overcrowding and the disease is disclosed; in fact, the death-rate from cancer, though nearly the same in all districts, is actually lowest in the most overcrowded. A satisfactory feature of the general statistics is that the infantile mortality rate declined to 116: in 1901 it was 148, so that it would really seem as though the educational work of the last few years has not been altogether wasted, and that if fewer babies are born, more care is taken of those that are. These statistics, and many others to which we hope to call attention on a future occasion are contained in Part I of the report. Part II deals chiefly with administrative questions. Reports on cerebro-spinal fever, on flies, on the homeless poor, and on sanitary staffs of metropolitan authorities appear as appendices.

INTERNATIONAL OPIUM COMMISSION.

WE have already announced that an International Opium Commission is to be held at Shanghai. The date of assembly has been postponed from January 1st to February 1st, 1909. We have received from the Secretary of the Society for the Suppression of the Opium Trade a copy of a translation of a circular letter of which the French original has been forwarded on behalf of the Society to the Foreign Minister of each of the twelve Powers (Great Britain, Germany, China, the United States, France, Japan, the Netherlands, Portugal, Russia, Turkey, Persia, and Siam) which have agreed to take part in the Commission. After relating what has been done in the matter, the letter summarizes the present state of legislation in various countries as follows: "In Japan, the Philippine Islands, and most of the self-governing British Colonies, the sale and consumption of the drug are totally prohibited, except for medical use. In China, a great effort is being made to free the Empire from this curse. In Formosa, most of the British Crown Colonies, Macao, and French Indo-China, beginnings, or at least promises, of legislation with the same object have been made. In British India the sale of opium prepared for smoking is prohibited, but that of opium for eating is permitted, except that in Burma it has been forbidden, since January 1st, 1894, to sell opium to Burmans and to certain other native tribes. In the Straits Settlements, also, the sale of opium to Malays is forbidden, but this prohibition, as also that exist-

ing in Burma, appears to be more or less evaded. In the Dutch Indies, where the sale of opium is a Government monopoly, the import and consumption of opium appears to be increasing year by year, to the great injury of the Javanese." The letter proceeds to state that "the cultivation of the poppy (*Papaver somniferum*) and manufacture of opium exist in Turkey, Persia, British India, and China. Turkey opium is preferred for medical use; in the United Kingdom chemists are bound by the directions contained in the *Pharmacopoeia Britannica* to use it exclusively. In Persia, according to the testimony of American missionaries and of a British consul, the cultivators are given to the opium vice, which reduces them to great misery. In India the cultivation has been diminished, in concert with China, which has undertaken to extinguish it entirely within ten years. There is a small amount of poppy cultivation and opium production, chiefly for local use, in the Punjab (Northern India), the Shan States (Burma), and Laos (between Siam and Burma)." The anti-opium societies are not satisfied with what has been done, as may be gathered from the concluding portion of the circular, where it is said that those who, in the United Kingdom, have long combated the opium traffic, whilst they recognize the great measure of progress effected by the Indian Government in undertaking to bring to an end the export of opium to China within ten years, provided the Chinese product is reduced *pari passu*, desire a far more rapid suppression. This, they say, would be so much the easier because, according to the annual reports of the officials in charge of the cultivation, the ryots find other crops more profitable than opium. They hold, too, that the action of Great Britain in bringing to an end a "morally indefensible" trade ought not to be conditioned by that of the Chinese Government. In view of Mr. Leech's statement that China is hampered by existing treaties in her attempts to put down the consumption of opium, they consider that all provisions in these treaties which restrict her freedom in this respect should be annulled. They express the hope that the Governments which participate in the International Commission at Shanghai will not hesitate to take the necessary steps to put an end as quickly as possible to the production and sale of opium except for strictly medicinal purposes. They conclude: "The traffic which supplies the non-medical use of this drug is condemned by medical science, and Japan has resolutely excluded it from her soil. It is reprobated by the moral judgement of the best elements in the Chinese Government and people. Western civilization cannot but sympathize profoundly with China in her supreme effort to free herself from this enervating and demoralizing scourge. The European nations having colonies or protectorates in the East cannot evade the duty of keeping pace with China. We trust that they will not content themselves with this, but regard themselves as bound in honour to set the example of speedy and effective prohibition."

THE BOMBAY MEDICAL CONGRESS.

THE Indian Medical Congress in Bombay will be opened on the morning of Monday, February 22nd, by the president, Sir George Sydenham Clarke, G.C.M.G., G.C.I.E., Governor of Bombay. The ceremony will take place in the Convocation Hall of the Bombay University, and the meetings of the various sections, by which the detailed work of the congress is to be conducted, will all be held within the university. Among the subjects specially selected for discussion are the etiology, prophylaxis, and treatment of plague,

enteric fever, relapsing fever, tropical diarrhoeas, and beri-beri; the differential diagnosis of various types of malarial fever and of dysentery, with suggestions for the prevention of these diseases; the pathological conditions due to the invasion of the Leishman-Donovan body, with suggestions for treatment and prophylaxis; the part played by animal parasites and disease carriers in the dissemination of diseases peculiar to the tropics; the clinical and pathological effects of the different varieties of snake venom; the pathology, distribution, and bacteriology of mycetoma; the bacteriology of leprosy and the results of special methods of treatment; the treatment of cholera; sanitation as applied to India; tropical surgery; and naval and marine hygiene, including quarantine and the incidence of tropical diseases among mariners. During the sitting of the Congress, there will be an exhibition of medical, surgical, and sanitary appliances, foods, and drugs, and a museum of pathological specimens, while a series of demonstrations will be given. These are primarily for the instruction of persons attending the Congress, but afterwards the exhibition will be thrown open to the general public for about three weeks. The Indian railway companies are granting special concessions to members of the Congress, and it is hoped that there will be a large attendance, and that much good work will be done. The General Secretary is Lieutenant-Colonel W. R. Jennings, M.D., F.M.S., of Bombay, and the Assistant Secretary is Captain E. F. Gordon Tucker. Among the Vice-Presidents are the Director-General of the Indian Medical Service, and the Principal Medical Officer His Majesty's Forces in India, as well as members of the Council of the Governor of Bombay, and the leading municipal officials of that city.

KISSING THE BOOK.

THE objections to what is known as "kissing the book" by way of winding up the taking of an oath in a court of law have been stated so often in these columns that in the recent revival of a discussion on the subject in the lay papers there seems something almost as mediaeval as the practice itself. On this occasion the topic has been started by a letter recording the acquirement of "malignant itch" of the chin, mouth, and throat through kissing the book. A scientific dermatologist might possibly be disposed to question this particular incident; but to do so would be mere pedantry, for it is indubitable that kissing the book is not only a nasty practice in itself, but a directly risky procedure. No one can deny that infection of one sort and another might readily be acquired by kissing, either on its cover or on one of its leaves, a volume which is habitually handled and used in the same fashion by persons of all stations in life, such as commonly appear in the witness-box. Various modifications of the practice have been suggested—such as the provision of a washable cover and of weekly supplies of new books—but none would assuredly be effective, nor would any of them be more easily introduced than that which practically is the only real remedy—namely, abolition of the practice altogether. There might be something to be said in favour of its preservation if there were anything particularly impressive in its character; but there can be no comparison between the moral effect on a witness of "kissing the book" by the order of a clerk of the court, who has just gabbled through a scarcely heard formula, and that of a witness raising his right hand and declaring in his own voice, "I swear by Almighty God as I shall answer to God" "at the great Day of Judgement that I will tell the truth, the whole truth, and nothing but the truth." The latter, though known as the Scottish oath, might be better described as the natural oath, for

such gestures as holding up the hand when making emphatic declarations have probably been employed by human beings since the world began. Of their special connexion with oath-taking there is evidence even in records as old as the Bible. In Genesis, for instance, a clear description of the taking of an oath by Abraham in this fashion may be found. How far back "kissing the book," on the other hand, can be shown to extend we are not aware, but it is akin to the kissing of images, and is probably a survival from pre-Reformation days. It is, of course, legally open to witnesses to adopt either one form of oath or the other, but of the comparatively few who are aware of this fact not all are prepared to make themselves conspicuous by standing out for the less accustomed form. Most of the exceptions are medical men influenced by a desire to see an insanitary practice abolished in the public interest. It has been suggested that the Scottish oath should be made compulsory by law, and some such course is probably necessary, for otherwise reform must continue to lie in the hands of officials who are for the most part too hide-bound by legal tradition to take the necessary action. An excellent instance in point was supplied last week by the Chairman of the Southwark Quarterly Sessions, who in addressing the grand jury admitted the drawbacks of the English oath and the simplicity and effectiveness of the Scottish form, but indicated that in his own court, at any rate, no step would be taken towards substituting the latter for the former as the habitual procedure. On the other hand, the judges of the Divorce Court are endeavouring to make the Scottish oath the customary form of swearing witnesses who may appear before them, and there have been among provincial magistrates during the past few years some honourable exceptions to the general rule.

THE ROYAL NAVY MEDICAL SERVICE.

THE Director-General of the Medical Department, Royal Navy, presided at a dinner held at the Criterion Restaurant, London, on January 8th, which was attended by seventy-three officers on the active and retired lists of the Royal Navy Medical Service. After the toast of "His Majesty the King" had been duly honoured, those present engaged in general conversation, and there were not a few instances in which officers then met for the first time since their probationary days at Netley and Haslar. Although the holding of such a dinner has often been talked about, this was the first time on which the scheme was realized, and the success attending this first effort will probably encourage those who took the matter in hand this year to organize similar dinners every year. Fleet Surgeon Lloyd Thomas, H.M.S. *Dædalus*, Bristol, would, we believe, furnish further particulars to any acting or retired naval medical officer who communicates with him.

SIR FREDERICK TREVES, BART., will deliver a lecture on radium in surgery, at the London Hospital Medical College, on Tuesday, January 26th, at 3 p.m.

ARRANGEMENTS have been made for the resumption of the work of the Medical Graduates' College and Polyclinic, 22, Chenies Street, London, W.C.; the first clinic of the new session will be held on Monday next, January 18th, at 4 p.m.

THE Morison Lectures before the Royal College of Physicians of Edinburgh will be delivered by Dr. F. W. Mott, F.R.S., at the College Hall on Monday, January 25th, Wednesday, January 27th, and Friday, January 29th, at 5 p.m. on each day. The subject of the course will be Syphilis of the Nervous System in the Light of Modern Research.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

HOSPITAL ABUSE.

THE *Manchester Medical Review* for December, 1908, contains an interesting and valuable paper on the hospital question, which was read by Dr. Arnold W. W. Lea before the Medico-Ethical Association. He found that in Manchester one out of every four of the population received hospital treatment during the year. He accepted the principles laid down by the British Medical Association as to the inability to pay for adequate treatment being the essential consideration for hospital treatment, and that investigation into the circumstances of applicants should be made in all cases. In Manchester the Charity Organization Society carried out such investigations on behalf of the Royal Infirmary, the Salford Hospital, Ancoats Hospital, and the Northern Hospital. In the last year 49,751 cases were investigated, and of these it was found that 2,099 were able to join the provident dispensaries while only 6 were able to pay for medical treatment. During the last five years less than 5 per cent. have been rejected as unfit for hospital treatment. Unfortunately it had not been possible to investigate the cases coming from outside towns which were very numerous, and there was little doubt that abuse often occurred among these. The standard of income rendering patients suitable for hospital treatment in Manchester was for single men or women 12s. to 15s. a week, and for married couples 18s. to 21s. with an allowance of 1s. 6d. for each child. The suitability for treatment depended on many factors, and he thought that the ultimate decision as to the fitness or otherwise must be given by the medical officer after he had been put into possession of the facts of the case. He was afraid that the inquiries made were often very imperfect, and at some of the special hospitals were made with the object of ascertaining how much the patient could afford to contribute to the expenses of the hospital treatment. In certain special hospitals the proportion of the total expenses borne by the patients amounted to almost one-third of the total income, and many of them could not keep their doors open if it were not for the contributions of the patients. He suggested that it was only fair that friendly societies and mutual insurance societies should pay some share in the expenses incurred by their members who receive treatment at hospitals, but so far no satisfactory scheme had been suggested. He saw no reason against the system of pay wards provided sufficient care was taken to limit them to deserving cases, but the suggestion that patients in pay wards should be attended by their own doctor could not be adopted under the present system of hospital management in large towns. The provision of provident hospitals was difficult owing to the great initial expense, but if established by the aid of municipal grants they would be of the greatest value, and could be made available for the use of all the medical men in the district. The essentials for checking hospital abuse he thought were:

1. Efficient inquiry by responsible officials, who should reject all obviously unsuitable cases.
2. In doubtful cases special visits should be made to the patients' homes and the results be recorded on the hospital cards, when the retention or otherwise of the patients should be determined by the medical officers.
3. A subcommittee of the hospital board should investigate all cases above a certain wage limit.
4. Patients should be asked to contribute according to their means.
5. Special hospitals should strictly confine themselves to their own line, but he saw no reason why patients should not contribute some portion of the cost of medicine and applications.

In the discussion which followed, it was stated that the question of hospital abuse was very pressing now in the Children's Hospital, where the new out-patient department, only opened eighteen months ago, seemed already too small for the work. To some extent this was due to the large number of school children advised to have tonsils or adenoids removed. Practitioners often refused

to do this operation and referred the parents to the hospital, though in many instances they could afford to pay several guineas for the operation. Several speakers dwelt on the difficulty of reform brought about by the fact that practitioners themselves so often sent patients to hospital whose circumstances disqualified them for hospital treatment. The position was summed up by one speaker, who said that less than two-thirds of the amount required yearly were obtained by charitable subscriptions; the rest had to be got on a commercial basis by the payments of patients, so that it came to this: that if the managers of hospitals put down hospital abuse, one-third of the income would disappear and the hospitals could not be carried on.

MEDICAL INSPECTOR OF SCHOOL CHILDREN AT BURY.

The Bury Town Council has again had under discussion the salary to be offered to the so-called Assistant Medical Officer of Health, whose duties will be really the medical inspection of school children. At the first council meeting, held on December 3rd, 1908, Mr. Alderman Parks, who said he was a member of the British Medical Association, referred to the fact that the advertisement offering a salary of £200 had been refused by the *BRITISH MEDICAL JOURNAL* and the *Lancet*, and he is reported to have said that if the medical journals boycotted the council it could go elsewhere, and that applications were already coming in. At the council meeting held on January 7th it appeared that only three applications had been received. The minutes of the Health Committee recommended an appointment to be made at £200 a year, and Alderman Greenhalgh in proposing that the recommendation be referred back argued that the salary was inadequate. He said that only three applications had been received owing to the fact that the principal medical journals had refused the advertisements, whilst one of these applicants on being offered the position had declined to accept it at so low a salary. Alderman Ashworth said that £200 was quite sufficient for men who were seeking opportunities to gain experience, while several speakers objected to any dictation by medical associations as to the amount of the salary. Councillor Turner thought that if they were going to appoint a man at a low salary simply that he might gain experience for positions elsewhere it would do away with the value of the medical inspection of children and would destroy the continuity that was essential to the success of the work. In the end the recommendation of the Health Committee was confirmed, and for the present the salary is to be only £200.

An awkward question has been raised, not only at Bury, but at other places—namely, when a medical man has accepted a position at £200 in opposition to the expressed resolution of the Association, does he deserve the support of the Association if he afterwards asks for an increase to £250? It has several times happened in the Manchester district, where there is a sort of consensus among respectable practitioners that no new clubs shall be accepted below 4s. a head per annum, that a practitioner has been willing to accept a club at even 3s. in order to get an introduction, and in a short time has applied for an increase to 4s., giving as a reason that the medical societies objected to clubs below 4s. The question then arises, Does such a man deserve to be supported by other medical men? Ought he not rather to be informed that if he chooses to act in opposition to the Association in the first place, he must not afterwards expect any support in applying for an increase in salary?

WALES.

GIFT BY THE CO-OPERATIVE CONGRESS.

The Newport and Monmouthshire Hospital has been presented by the Co-operative Congress with three dozen bed-tables for the use of patients, each bearing the following inscription:

Blandford Memorial. Presented by the Co-operative Congress at Newport, Mon., on June 8th, 9th, and 10th, 1908, in memory of a fellow worker.

The Blandford Memorial Fund, to which each delegate to the Congress subscribes 1s., maintains a scholarship and also makes a contribution annually to the charities of the district in which the Congress meets.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

SCOTTISH UNIVERSITY WOMEN AND THE FRANCHISE.

IN Edinburgh there was recently held the final meeting of the Committee of Women Graduates of the Scottish Universities (Parliamentary Franchise), to wind up the affairs of the committee and to discuss the advisability of forming a Scottish Universities Women's Suffrage Association. Miss Frances Simpson presided. It was reported that the total legal expenses incurred in the unavailing effort to get the university franchise amounted to £1,200, and that the amount subscribed left a deficit of £70. It was decided to dissolve the committee, and resolved that university women should work for women's suffrage. It was further agreed that the University Women's Suffrage Association should be a separate organization from other bodies, as this would best help the cause. A provisional committee was formed and a subcommittee was appointed to discuss the constitution of the new society. The provisional committee will meet on January 16th to discuss the constitution to be then submitted. The members, representing all the Scottish universities, were entertained by the women students.

ABERDEEN HOSPITAL SUNDAY.

The annual collection for the Royal Infirmary was made in the various churches of Aberdeen on January 3rd. The total collection at 53 churches and meeting places was £988 17s. 10½d., against £1,059 13s. 3½d. at 59 last year.

HEALTH AND GROWTH OF SCHOOL CHILDREN.

The reports of the medical officers to the Govan School Board for the year ending June, 1908, contain some information of general interest. The attention of the medical officers was directed to the condition of the children as regards height and weight, and some valuable statistics were collected.

It was found that there is a very close connexion between the environment and the physical condition. This was clearly brought out if the children were arranged in three classes according to the school attended. In the schools belonging to Class I the children are drawn from the families of commercial, professional, and other well-to-do classes, where the hygienic environment is good, and parental neglect does not exist. Class II includes schools where the children belong to the upper artisan, retail shop-keeping, and lower commercial classes; while Class III represent children of the working class and of the very poorest social scale. On comparison with the standard laid down by Dr. Leslie Mackenzie in his book on *The Health of the School Child* marked fluctuations and differences appear. The comparison is rarely in favour of the Govan child. The difference is least when the child is young, and becomes steadily more pronounced as the child reaches the age of 10, especially in the case of the children forming Class III. It is rather noteworthy that the girls correspond much more closely to Dr. Mackenzie's standard than the boys.

The general average height of the Govan boy is at the age of 5 years only a fraction of an inch behind Mackenzie's standard; at the age of 6 it is 1½ in. below the standard; at 7, about 2 in.; at 8, 1½ in.; at 9, over 2 in., and at 10 years of age it is 4½ in. below the standard. The average height of the girls is slightly above the standard at 4 years; from the sixth to the ninth years it remains 0.9 in. below the standard, when it drops to 1½ in. below, and at 10 years of age it is 2.1 in. below the standard. Thus, the average height of the girl of 10 is fully an inch greater than that of boys of 10.

The weight also fails to reach Dr. Mackenzie's standard, but here, too, the girls approach the standard weight more closely than the boys. At 5 years of age both boys and girls are practically of standard weight, but at 8 years of age the Govan boy is already 4.2 lb. behind the standard, while at 9 years the deficit is 6.7 lb., and at 10 years no less than 10.6 lb., when the average weight of the Govan boy is actually 4 lb. lighter than that laid down by Dr. Mackenzie for a girl of the same age. The Govan girl's weight line is much more satisfactory than that of the boys. Agreeing with the standard at 5 years of age, at

8 it is 3 lb. behind, and at 9 nearly 4 lb., and at 10, 6 lb. behind the standard.

The marked average deficiency in both height and weight is due largely to the influence of the Class III school. When the average of the schools in Class I is separately examined it is found that the average heights correspond very closely to the standard. Up to 9 years of age it is above that standard, but at 9 years it is about 1 in. below, and at 10 years 1.3 in. below. The average of the boys in Class II approximates very closely to Class I, but is always below it, and at 10 years of age is 0.7 below Class I, or 2 in. below standard. The average for Class III is markedly below the other two classes, and at 10 years of age is 4.4 in. behind Class I, and 5.74 below standard. In Class I the average height of the girls is above the standard, except for 10 years of age, when it is a fraction of an inch behind. Girls of Class II are 1½ in. below standard at 9 years, and 1.6 in. below at 10 years. It is again in Class III that the most marked difference is seen, when at 10 years the girl is 2.6 in. below standard height.

The weights for boys in Class I is practically the same as Dr. Mackenzie's standard until the ninth year, when it is 2.6 lb. below standard, and at 10 years 6.8 lb. below. Class II is below the standard, except at 5 years of age, and at 7 years in 2.6 lb., and at 10 years 9.5 lb. below standard. In Class III the deficiency is even greater. Thus, at 5 years the drop is 1 lb., and at 10 years the deficit is 11.7 lb.

The girls' weights in Class I are above standard at 5 and 6, and thereafter approximate closely to standard till the age of 10, when a drop of 3.4 lb. is seen. In Class II the weight is slightly below standard till the seventh year, when a drop of 1.6 lb. is noted, increased at 8 years to 3.5 lb., and at 9 is about 3 lb., while at 10 it is 3.6 lb. below standard. Class III is throughout below the standard—most markedly so at 10 years of age, when the deficiency amounts to 7.4 lb.

It was, of course, to be expected that rickets and parasitic skin diseases would be much more prevalent in the lower-class schools than in the schools of Class I, but one was hardly prepared for the statement that the teeth of children in Class I schools were not markedly superior to those of children in the other classes.

Ireland.

[FROM OUR SPECIAL CORRESPONDENT.]

JUDGE AND DOCTOR.

A DUBLIN newspaper publishes the following, regarding an unpleasant incident before the County Court judge:

A point of interest to the medical profession was raised at Clones Quarter Sessions by Dr. Edward Tierney, J.P., who, being present in court, was called by the judge (His Honour County Court Judge Craig) to give evidence in a case where damages were sought for assault.

Dr. Tierney objected to give evidence unless he got his fee or a promise of it.

His Honour: It is your duty to be sworn.

Dr. Tierney: I decline to be sworn.

His Honour: Very well; I will commit you for contempt.

Dr. Tierney: I can give no material evidence.

His Honour: That does not matter. I will make out an order.

Subsequently His Honour fined Dr. Tierney £2 for contempt. Dr. Tierney was commencing to speak, when His Honour said he would not hear him. Dr. Tierney persisted.

His Honour (to the police): Remove that man.

Dr. Tierney was understood to say that it was not for the sake of the fee, but for the sake of the medical profession, that he objected.

The incident then ended.

In this report we have not all the particulars before us, but we should like to know whether a judge can force a witness, who appears to have been in court by accident, to give evidence in a civil action for damages. Whether that is so or not, Judge Craig seems to need some instruction in the gentler methods of dealing with persons in his court. There does not appear to have been anything which could not have been settled by an explanation. Even the desire to show authority might be exercised without unnecessary brusqueness.

LUNACY IN IRELAND.

The fifty-seventh report of the Inspectors of Lunatics for Ireland for the year 1907¹ shows that the certified insane on January 1st numbered 23,554, and on December 31st, 1907, 23,718, giving an increase for the year of 164 as compared with the increase of 189 for the preceding year, the increase for 1907 being 295 less than the average increase for the preceding ten years, which was 459. These figures do not include the insane wandering at large nor those residing in private dwellings, with the exception of Chancery patients. The insane at the end of 1907 were distributed as follows: In district and auxiliary asylums, 19,511; in Dundrum Criminal Lunatic Asylum, 158; in private asylums, 870; in workhouses, 3,053; and Chancery patients, 126. With regard to the proportionate distribution of the insane in Ireland the inspectors furnish a table which shows that, as in England, there has been for some years an increasing proportion maintained in district and auxiliary asylums and a diminishing proportion in workhouses; thus, whereas in 1880 there were 67 per cent. in district and auxiliary asylums, 27 per cent. in workhouses, and 6 per cent. in private asylums, in 1907 there were 82 per cent. in district and auxiliary asylums, 5 per cent. in private asylums, and only 13 per cent. in workhouses.

The Increase of Insanity in Ireland.

Although the statistics show a numerical decrease in the rate of increase in the certified insane in Ireland, there has been, as in England, a steady increase in the ratio of the insane to general population, for it is to be remembered that in Ireland there has been for many years a steady decrease in the general population. From a table furnished by the inspectors, we see that in 1880 there were 12,932 lunatics under care, giving a proportion of 250 per 100,000 of general population, or 1 in every 400.7 of general population, whereas in 1907 there were 23,718 lunatics, giving a proportion of 542 per 100,000 of population, or 1 in every 184.5, as compared with the 1 to 280 of England and Wales on the same date. Doubtless to some extent increased certification amongst the uncertified reserve revealed by the census returns accounts for this great increase. Thus, from figures supplied by the inspectors we see that the differences between the numbers of lunatics and idiots obtained at the censuses of 1831, 1891, and 1901, and those officially known to the inspectors in these same years were 5,087 in 1831, 4,500 in 1891, and 3,420 in 1901. This does not, however, explain the great increase, for we see that, considering the total insane and idiot, certified or at large, as revealed by the census returns, their proportion to population rose from 1 in every 230.5 in 1831 to 1 in every 177.4 in 1901. A theory which we have sometimes seen advanced to explain Ireland's high ratio of insanity is that constant emigration drains the country of her young and vigorous peasant stock. In relation to this plausible explanation, an interesting report was issued last year by the United States Census Bureau, giving the results of their twelfth census, from which it appears that the Irish immigrants into the United States give a higher ratio of insanity than those of any other country. Probably, however, the increase in Ireland's insane is due to the same cause which appears to be operative in England and Wales—that is, accumulation from declining death and recovery-rates—for we see that since 1903 the total admission-rate to asylums in Ireland had fallen from 90 to 81 per 100,000 of population, and the ratio of first admissions to asylums from 71 to 63 per 100,000 of general population. As already stated, the insane in Ireland are distributed over district and auxiliary asylums, private asylums, the criminal lunatic asylum at Dundrum, and in unlicensed houses as Chancery patients. As the statistical information supplied to the office of the inspectors of lunatics concerning these separate classes does not follow one uniform plan, we are compelled to treat these classes separately.

District and Auxiliary Asylums.

On January 1st, 1907, there were 19,306 in these institutions, and on December 31st, 1907, there were 19,511, giving a total increase of 205 for the year.

Admissions.—During the year 3,554 were admitted, as compared with 3,524 for the previous year and 3,772 for 1905. Of the total number of admissions, 709, or 19.95 per cent., were admitted to district asylums from workhouses. Of the total admissions, also, 2,745 were first, and 809 not-first, admissions. The readmissions thus formed 29.4 per cent. of the total admissions. As regards duration of disorder on admission, in 1,591 the attacks were first attacks within three, and in 448 more within twelve months of admission; in 649 not-first attacks within twelve months of admission; in 560, whether first attacks or not, of more than twelve months' duration; and in the remainder the attacks were either of unknown duration (185) or of congenital origin (121). The admissions were classified according to the forms of mental disorder into: Mania of all kinds, 1,702; melancholia of all kinds, 1,271; secondary, senile and organic dementia, 166; primary dementia, 27; general paralysis of the insane, 61; epileptic insanity, 144; and congenital or infantile defect, 161. A noteworthy feature of the above list is the small number of general paralytics, constituting roughly only 1.7 per cent. of the total admissions, or 2.7 per cent. of the male and less than 0.5 per cent. of the female admissions, whereas in England and Wales the general paralytics form 6.8 per cent. of the total, or 11.6 per cent. of the male and 2.2 per cent. of the female admissions. Formerly this disease was almost unknown in Ireland, and even yet, the inspectors say, it is more rarely met with than in any other country in Europe, and is practically limited to the cities of Dublin and Belfast.

Causation.—Alcohol was assigned as the probable cause of insanity in 383, that is in 10.7 per cent. of the total, or 15.3 per cent. of the male and 5.2 per cent. of the female admissions, as compared with the 21.9 per cent. of the male and 8.9 per cent. of the female admissions in England and Wales. Venereal disease was assigned in 58, that is, in 1.6 per cent. of the total, or in 2.6 per cent. of the male and 0.4 per cent. of the female admissions, as compared with the 5.3 per cent. of the male and 0.9 per cent. of the female admissions in England and Wales. Alcohol and syphilis thus appear to play a much less important part in the causation of Ireland's lunacy than in England and Wales. Other assigned causes were: Critical periods in 195, pregnancy in 67, various bodily diseases and disorders in 177, previous attacks in 314, and mental and emotional stress in 311. Hereditary influences were ascertained in 969, or 27.0 per cent., and congenital defect was recorded as cause in 145, or 4.0 per cent.

Discharges and Deaths.—During the year 1,371 were discharged as recovered, giving a recovery-rate on the admissions of 38.6 per cent. (males 39.8 per cent., females 37.1 per cent.), or on the average (daily number resident of 7.1 per cent. (males 7.4 per cent., females 6.7 per cent.)). These recovery-rates are slightly higher than those in England and Wales in 1907, though unlike England and Wales they were higher in the male than in the female class. There were also 408 discharged as relieved and 79 as not improved, or not insane or insanity doubtful. During the year 1,486 died, giving a death-rate on the average number resident of 7.7 per cent., as compared with the 10.1 per cent. of county, district and county borough asylums in England and Wales. Of the total deaths 1,479 were from natural causes, 3 dying from accident and 4 by suicide. The deaths were due in 434 instances to cerebrospinal diseases, including 74 deaths from general paralysis; in 729 to chest diseases, including 400 from pulmonary consumption; in 96 to abdominal diseases; in 220 to general diseases, including 100 from senile decay and 30 from general tuberculosis; and, as above stated, 3 from accident (1 by poisoning and 2 by cut-throat). It will be noted that the deaths from general paralysis amounted to only 4.9 per cent. of the total deaths, as contrasted with the 16.8 per cent. of England and Wales. On the other hand, the deaths from pulmonary consumption and other forms of tuberculosis formed 28.3 per cent. of the total deaths, as compared with 16.89 per cent. for the same year in England and Wales. Commenting on this high death-rate from tuberculous disease, the inspectors say that there can be no doubt that many cases develop in the asylums, and add:

Moreover, it is not to be assumed that the figures given in our statistics can be taken as embracing the whole amount of tuberculous disease existing amongst the insane, as the immediate

¹ The Fifty-Seventh Report of the Inspectors of Lunatics (Ireland) for the Year ending December 31st, 1907. Dublin: Alex. Thom and Co., Abbey Street. 1908. Price 1s.

cause of death in the case of patients affected with phthisis is frequently some other intercurrent disease, and therefore the existence of tuberculous affection is not disclosed in the statistics. Owing to the small number of *post-mortem* examinations made in Irish asylums, the presence of tuberculous disease, which may not be the cause of death, or may not be discoverable during life, is never brought to light—a circumstance which accentuates the importance of these examinations in obtaining accurate information on this point, as well as on the pathology of insanity generally.

Having regard to the great overcrowding which still exists in many of the district asylums, it cannot be doubted that the conditions under which the patients live in these institutions are in themselves specially liable to spread tuberculous disease amongst those susceptible to its contagion, and that ample accommodation provided in well-ventilated buildings would do more than anything else to lessen the ravages of the disease, which at present is more fatal than any other in Irish asylums, and is liable to be carried from them and disseminated amongst the general population.

Average Cost.—The average cost per patient per annum, excluding charges in respect of buildings, land, etc., calculated on the gross expenditure, less loan repayments, receipts from miscellaneous sources and receipts on behalf of paying patients, was for district asylums, £21 19s. 3d., and for Voughal Auxiliary Asylum, £16 18s., showing a reduction in the case of the district asylums and an increase in the case of the auxiliary asylum as compared with the amounts for the previous year.

Private Asylums.

In Ireland accommodation for the insane who are able to contribute towards their maintenance is provided in licensed houses, of which there are 12; in mental hospitals, not kept for profit, of which there are 4, and a certain number are received into district asylums. On January 1st, 1907, there were 845 patients in the 16 private asylums, and on the last day of the year there were 870. During the year 276 were admitted, of whom 213 were first and 63 not-first admissions. No information is supplied as to duration of disorder on admission, but with regard to the forms of mental disorder they were classified as follows: Mania of all kinds, 80; melancholia of all kinds, 113; secondary, senile, and organic dementia, 24; primary dementia, 4; general paralysis of the insane, 9; epileptic insanity, 3; and cases of congenital or infantile defect, 23. The general paralytics thus formed 3.2 per cent. of the total admissions, a proportion twice as great as that of the pauper class. The table setting forth the probable causes of insanity among the private patients refers, not to the admissions, but to those remaining in the asylum at the end of the year, and are thus of little use for comparative purposes. We may say, however, that alcohol was assigned as cause in 87, or in 10 per cent., of the 870 remaining at the end of the year. During the year, 83 were discharged as recovered, giving a recovery-rate on the admissions of 30.1 per cent., being 8.5 per cent. lower than the recovery-rate of the district asylums, instead of being as much above it as is the case in England and Wales. There were also 54 discharged as relieved, and 40 as not improved. During the year, 73 died, 70 from natural causes and 3 by suicide, the total deaths giving a death-rate on the average numbers resident of 8.5 per cent. Unfortunately no table is furnished showing the causes of death in the private asylums.

State Criminal Lunatic Asylum, Dundrum.

In this institution on January 1st, 1907, there were 162 patients, and on the last day of the year there remained 158. During the year 15 were admitted, of whom 3 were found insane on arraignment; 4 were acquitted of the offences on which they were charged on the ground of insanity or were found guilty but insane, and 8 were convicts who had become insane whilst undergoing terms of penal servitude. Of the 15 admissions, 2 were readmissions and the remainder were the subjects of first attacks, or no information was obtainable on this point. They were classified according to the forms of mental disorder into: Mania, 6; melancholia, 1; dementia, 3; idiocy, 1; and insanity doubtful, 4. No information is supplied concerning the supposed etiological factors, but as to the crimes committed, 6 had committed or attempted to commit murder or manslaughter, 2 rape, 2 burglary, etc., 4 arson or malicious injury, and 1 attempt at suicide. During the year, 8 were liberated or given over to the care of friends, and 10 transferred to district asylums. Only

1 died during the year, the cause of death being pneumonia.

Persons of Unsound Mind in Irish Workhouses.

On January 1st, 1907, there were 3,238 persons of unsound mind in union workhouses, being composed of 1,889 lunatics and 1,349 imbeciles. Of the total number, however, 110 were lunatics boarded out in workhouses from Antrim, Belfast, Ennis, and Londonderry asylums. On December 31st, 1907, there were 3,156 in workhouses, of whom 103 were boarded out from the above-named asylums, showing a further decrease in the number of the insane in these institutions. The inspectors show that the condition of the insane inmates of workhouses in Ireland urgently calls for improvement.

Sydney.

[FROM OUR SPECIAL CORRESPONDENT.]

INFANT LIFE PRESERVATION.

THE Medical Officer of Health for Sydney some four years ago laid before the City Council a plan for inducing a larger number of mothers to feed their infants from the breast, and the council at once authorized the addition to its staff of a woman inspector to act within the city boundaries. A report on the result of this system during the past four years or more in which it has been tried was presented to the Board of Health at a recent meeting. Between July 1st, 1904, and December 31st, 1907, 4,748 nursing mothers in the city were visited by the inspector: this represents 52 per cent. of all births registered, and 67 per cent. of all births which occurred outside public institutions. The average age at which these newborn children were visited was 5.3 weeks. The inspector's duty was to diffuse some general knowledge among the more ignorant of the methods and precautions necessary for the rearing of the babies, but her chief duty was to recommend that they be fed exclusively from the breast. The results have been as follows:

	1904.	1905.	1906.	1907.
Number visited	781	1,455	1,240	1,272
Breast-fed only	564	1,114	977	1,019
Partial breast-fed	166	250	210	202
Not breast-fed	51	91	53	51

The beneficial results of the diminution in the number of infants not breast-fed is reflected in the steady diminution in the infantile mortality-rate, as shown in the following table:

Year.	Death-rate.	Year.	Death-rate.
1901	1.55	1905	0.64
1902	1.86	1906	0.73
1903	1.83	1907	0.81
1904	0.96		

Dr. Armstrong, the city health officer, pointed out that there were many adjacent populous suburbs to which at the present time there was no opportunity of extending this beneficial plan, and proposed that a second woman inspector should be appointed to exercise similar functions in these populous districts. The Board of Health at once accepted his recommendation, and unanimously decided that the Government should be requested to appoint another woman inspector.

AUSTRALASIAN MEDICAL CONGRESS.

At the concluding meeting of the eighth session of the Australasian Medical Congress held in Melbourne in October, 1908, it was unanimously decided that the next session should be held in Sydney in 1911, and Dr. F. Antill Pockley, lecturer in ophthalmology in the University of Sydney and ophthalmic surgeon to the Royal Prince Alfred Hospital, Sydney, was elected president.

Natal.

NATIVE DOCTORS.

SOME recent events have again attracted attention to the existence and customs of native doctors. These men are at present accorded a definite standing by the Legislature; indeed, for all practical legal purposes their position scarcely differs from that of fully-qualified European practitioners. Like the latter, they are expected to take out an annual licence, for which the Government receives a fee of £3, and their legal recognition is so complete that within recent times certain members of this class have been allowed to use the law courts for the enforcement of the payment of fees from patients. Nevertheless, they are, so far as real medical knowledge is concerned, natives pure and simple, whom it would not be easy to differentiate from the tribal "doctors," okeah men, and witch finders of the West Coast of Africa. In spite of their ignorance, however, they are able, as a recent trial revealed, to get hold of the most powerful European poisons, and case after case during the past few years has shown that they are a danger to the public in other ways. Many charges of murder have originated owing to their existence, and though the accused have not always been found guilty, the trials left little room for doubt that murders are from time to time committed with a view to obtaining the heart and other parts of the human body, which in native medicine are considered of value in treatment. Furthermore, the Dinizulu inquiry and other investigations into the circumstances attending the last Kafir rising suffice to show that men of this class exercise a strong influence over native minds, and that "doctoring for war," in which human blood and bones play a part, is still in existence. Men of the same type are doubtless to be found in all semicivilized areas, but when a colony has reached a development such as that of Natal it is difficult to believe that they are any but a retarding influence, helping to keep up customs and habits which, in the interest of all, should pass away. In any case, we know of no other British possession in which such persons are not only suffered by the authorities, but actually recognized and protected by them. Doubtless they would continue to exist and practise their arts for some time to come, whatever steps were taken, but at least the Government should refuse its countenance to them, and for its own credit and repute cease to make a profit out of their existence.

ANKYLOSTOMIASIS.

As recorded in a recent issue, ankylostomiasis is not only causing a considerable degree of suffering among the imported coolies and a great deal of expense to their employers, but is now known to have attacked several Europeans. The mortality returns for November in the Durban area suggest, indeed, that possibly the disease is more rife among Europeans than has hitherto been suspected. The total death-rate for Durban is shown to be only 13.3 per 1,000, which, so far as it goes, is entirely satisfactory; but, on the other hand, nearly 20 per cent. of the whole of the deaths amongst Europeans are ascribed to that vague condition known as marasmus. Two or three years ago this term and its analogues—such as general debility and wasting—used to figure frequently in the reports concerning the Indian population, and there is little doubt now that in many cases they covered deaths from ankylostomiasis, a disease at that time not known to have been imported from India. It seems possible, if not probable, that some of the deaths now attributed to marasmus in the European returns are due to the same cause.

Mauritius.

THE PUBLIC HEALTH.

THE Colonial Office report on Mauritius is by no means encouraging. With an overplus of population and the island at its maximum of productivity, "the future," it is stated, "must give cause for anxiety." Poverty is undoubtedly on the increase, and there is a general tendency towards pauperism, while the plague and the

epidemic of surra among the equines still linger. Poverty is stated to be in great measure answerable for the unsatisfactory condition of public health, but there is, nevertheless, an improvement upon the preceding year. The birth-rate has increased to 37.6 per mille, and the death-rate has fallen from 40 to 34.7. The total population of the island is 377,644, of whom nearly 264,000 are Indians. For some years past there has been an increase in the latter and decrease in the Creole population.

Malaria accounted for 4,262 admissions to the hospitals, a considerable increase on the previous year, and dysentery, with 1,286 admissions, is nearly double that of 1906. Charts are given to show that the curve of the rainfall and that of malaria are practically identical, the number of cases rising steadily from February to April, and then rapidly diminishing to a minimum in September. A similar chart shows the coincidence of dysentery with the rainfall until July, when a prolonged drought set in until November; the consequent stagnation and pollution of the streams was attended by a high prevalence of dysentery and diarrhoeal disorders. Altogether 23,355 cases were admitted into the fourteen hospitals, in addition to the 55,635 persons treated in the dispensaries, an increase of 3,000 over the previous year's figures. It is noticeable that tuberculosis is on the increase. Beri-beri, which is not endemic in the island, broke out simultaneously in three out of the four prisons, and the infection was ascribed to the use of a decorticated unstored rice from the East. The epidemic at once subsided on changing the diet to bread at first, and then to ordinary Indian rice. Plague came to the island in 1899, and since then there have been 6,740 cases and 5,155 deaths, giving a death-rate of 76 per cent. of cases attacked. This is very steady, the highest in any year being 81, and the lowest 73 per cent. The year 1907 is noteworthy as recording only 224 cases, the lowest since the introduction of the disease. A strenuous campaign against rats was kept up, and 125,000 destroyed by the Government ratcatchers. A most important feature of the year was the establishment of a bacteriological laboratory, in which much research work with regard to surra has been done.

Special Correspondence.

PARIS.

The Retiring President of the Academy of Medicine.

*—Treatment of Disseminated Sclerosis by X Rays.—
Diagnosis of Enlarged Intertracheo-bronchial Lymphatic
Glands.—Treatment of Cerebro-spinal Meningitis.*

AT the first meeting of the Académie de Médecine for 1909, M. Bucquoy, the retiring President, passed in review the work of the year, calling special attention to the communications of M. Calmette of Lille on the ophthalmic diagnosis of tubercle, of Professor Vaillard on preventive injections of antitoxin serum in the prophylactic treatment of tetanus in man, and the report of M. Vidal on epidemics, notification and disinfection. M. Léon Labbé, who is a member of the Senate, then took the presidential chair, and Professor Dieulafoy took his seat as vice-president, to which office he was recently elected.

Professor Raymond presented a report on a paper by Professor Marinenco of Bucharest on 2 cases of disseminated sclerosis which had been improved under radio-therapeutic treatment. He had been led to use the treatment owing to the good effects obtained from x rays, especially in cases of syringomyelia, by Raymond, Babinski and others:

CASE I.—A young man, aged 29, had sixteen sittings. There was a notable improvement in the majority of the troubles of motility; the trembling in the upper limbs disappeared almost completely and the patient could carry a glass of water to his lips; he began to write again, speed improved, and muscular strength increased. The walking also improved, but to a less noticeable degree.

CASE II.—A young woman, aged 25, had eight sittings, followed by improvement in walking and diminution of the trembling; she walked with less hesitation and with less fatigue than formerly.

The treatment was applied every other day at the level of the lumbar region. The patients were exposed for seven

to ten minutes on each occasion, the distance from the focus being 15 centimetres and the intensity 1 milliampère. The quantity of rays corresponded to 5 h, and the quality to 7.5 to 8. No skin troubles were noticed. The method was free from danger and should be further tested.

M. Martin du Maguy, of Bordeaux, in a paper on the character of the cough and the distant voice as pathognomonic signs of compression of bronchial tubes from any cause, said these can be observed early, are easy to find and are proportional to the intensity of the compression. The patient is seated, directed to cough, and to repeat the number 333, which in France appears to replace the familiar 99. The physician auscultates the back of the chest, listening alternately at the apex and at the base, over the last intercostal spaces in the scapular line. At the base the sound is distant, and it is easy to diagnose enlarged intertracheo-bronchial lymphatic glands by this method.

At a recent meeting of the Société Médicale des Hôpitaux M. Arnold Netter read an interesting paper on the results of the treatment of cerebro-spinal meningitis. Since 1899 he had treated 36 cases (32 in hospital and 4 in private practice); 14 cases were fatal, giving a mortality of 38.9 per cent.—much lower than the majority of statistics published, which, he said, ranged from 60 to 80 per cent. The only cases included were those in which lumbar puncture had shown a purulent fluid, and in which bacteriological examination revealed the presence of the diplococcus of Weichselbaum. The cases were most numerous in 1899 and in 1908. Six occurred in Russian children, who seemed very susceptible to the disease. The male sex was more affected, giving 28 cases to 8 females. The disease was especially prevalent in the spring and during the cold weather—9 cases in March, 5 in January and April, 3 in February and December. (1) *From 1899 till the end of 1902* M. Netter treated all his cases by prolonged hot baths and repeated lumbar punctures. The hot baths had a favourable influence on the excitement, the pain, and the contractures. The repeated lumbar punctures acted by diminishing the dangers from an accumulation of cerebro-spinal fluid, and by removing an important portion of the microbes and their products. Sixteen patients were treated by this method, with eight deaths, a mortality of 50 per cent.; four children under 2 years of age all died; in children from 2 to 5 years of age the mortality was 33 per cent.; over 5 years M. Netter had two cases—a child of 7 years, who died after three months' illness, and a young woman of 22 years, who was completely cured after a lengthy period. (2) *At the end of 1902* M. Netter began the use of colloidal silver, concurrently with hot baths and lumbar punctures in twenty cases, with nine fatal cases, giving a mortality of 42 per cent. Eliminating the cases which also received antimeingococcic serum, and counting only the hospital cases, the mortality before the use of collargol was 53.9 per cent.; after the introduction of collargol the mortality was 43 per cent. M. Netter found that the introduction of collargol into the cerebro-spinal canal was not advantageous; he obtained better results by its intravenous injection, the explanation being that collargol was not principally a bactericide, but activated the defensive processes in all the organs. (3) *Since the introduction of antimeingococcic serum* M. Netter has treated five cases. Two children aged 3 and 4 months were not included in the statistics, as in one case it was impossible to introduce the serum into the cerebro-spinal canal, and in the other only a minimum dose could be injected; both these cases terminated fatally. The three remaining cases were aged respectively $3\frac{1}{2}$ years, 3 years, and 16 months. Two of them recovered; the first received two intraspinal injections of 10 c.cm. of the serum of Wassermann, and the second received one injection of 10 c.cm., and an injection of 20 c.cm. of the serum prepared by Dopter at the Pasteur Institute. The third case succumbed; it had only received one injection of 10 c.cm. on the twelfth day of the disease when the child was admitted to hospital in a very grave state, the condition being complicated by a serious mastoid disease with peripheral facial paralysis. In this case also the microbes in the cerebro-spinal fluid differed from the diplococcus of Weichselbaum in that they did not ferment sugar and did not agglutinate with serum. The two successful cases were not sufficient to prove the efficacy of the serum, but the effects of the second injection in one case was so

rapid and striking that M. Netter considered the relation of cause and effect most probable. M. Dopter, who followed M. Netter, insisted on the necessity of introducing the serum by lumbar puncture, after withdrawing a quantity of cerebro-spinal fluid equal in quantity to the serum to be injected.

Correspondence.

THE DRAFT CHARTER AND THE REFERENDUM.

SIR,—It appears to me to be obligatory on all of us who are anxious for the success of the application for the Charter to endeavour to bring to an end the present unfortunate difference of opinion as to the means to be adopted in the future for obtaining a Referendum of the members on any points of dispute that may arise. It has frequently been suggested by their opponents that the persons who are in favour of a letter Referendum to each member and a bare majority of the Council are few in number and take no active interest in the general work of the Association. I trust I shall not be misunderstood if I say that I think the latter suggestion, at any rate, would not apply to me. As Secretary of the Bradford Division for the first five years after its inception, and as one who has hardly missed a meeting of committee or of the Division for the whole of that time, I can certainly plead that I have in every way endeavoured to further the interests of the Association. My opinion now is that the vast majority of the members of the Association are in favour of a letter Referendum and that the decision to take this should be by a bare majority of the Council. It is certain that if the Charter is maintained in its present form it will be actively opposed before the Privy Council, and that the petition to grant it will be absolutely rejected until an agreement is arrived at. This would be a grave misfortune, and might possibly imperil any future application for a Charter that might be made.

I would propose that, as the suggestion for endeavouring to obtain an alteration on the two points in dispute, after the grant of the Charter, does not meet with approval, the Council should immediately, on its own initiative, or that three constituencies should requisition it, to call together a Special Representative Meeting to agree to the proposals put forward. The expense incurred will be nothing in comparison with what will be spent if the Charter is pressed forward as it stands. A united representation could then be made to the Privy Council for the alteration of the clauses as desired, and I have no doubt that in due course we should obtain our Charter.

How much better would an ending of this kind be than the one that is sure to result if we appear to differ amongst ourselves!—I am, etc.,

JAMES METCALFE,
Vice-Chairman of the Bradford Division.

Bradford, Jan. 9th.

SIR,—I think it most unfortunate that Mr. Ballance should have written as he has with reference to our esteemed President, for most of us thought that he (the former) was one of the coolest and most moderate of our forward men; but the fact of the matter is that all of them are so enraptured with the idea of the Charter they are ready to devour any one who stands in their way. They are too much in a hurry, and cannot look to the right or the left. We are certain to have a Charter, therefore let us make it as safe and sound and broad as we possibly can.

We may be quite certain that the President would not have acted as he has without very good reason, and the Branches are really confirming the necessity for this action every week, so that I consider Mr. Ballance's letter would have been better unwritten.

His action might have been more justifiable if the President had taken isolated action, but it is not so, for not only are the Branches moving, but the Past-President and the President-elect hold the same views.

I consider Mr. Ballance's letter more the work of a party man than of a statesman, and that it is the help and guidance of men of the latter class that we most require in all things pertaining to the application for a Charter.

Writing such a letter is setting an extremely bad precedent, for attacking the President as he has only makes

other Representatives call to mind how it came about that he himself was elected Deputy Chairman; but it would be exceedingly unwise to follow his example, as it would only resolve itself into a throwing of stones all round, much to the loss of dignity to the Association. I trust Mr. Ballance will see his error.

I certainly hold that there has been undue haste in lodging the application for the Charter under the unsettled condition of opinion in the Association upon the subject. I do not hold with Mr. Ballance that the President is opposed to the granting of a Charter at all.—I am, etc.,

Manchester, Jan. 11th.

G. H. BROADBENT.

SIR.—The letter of Mr. Simeon Snell, published in the *BRITISH MEDICAL JOURNAL* of January 2nd, must have opened the eyes of many to the gravity of the situation that has been created by the precipitancy with which action has been taken in the matter of the Charter by a few officials and others in the name of the Association. The fact that the petition does not bear the signatures of the President, the Past-President, or the President-elect, is sufficiently remarkable in itself to give pause to the ardent spirits who have hurried on a step which should have been taken only in response to the wish of an overwhelming majority of the Association. How small a part is really represented by the signatories to the petition is becoming more and more manifest as the votes of the Branches, given in response to a genuine Referendum, are recorded almost week by week in the *JOURNAL*. The tone of the letters, which in your editorial impartiality you have published from both sides, also reveals a striking difference between the men who counsel delay and deliberation in an enterprise of the greatest moment, and the "insolent and aggressive faction" (if I may borrow John Henry Newman's famous phrase) who brand all who venture to differ from them as "disloyal," "unconstitutional," and apply to them the other terms of abuse which are the usual weapons of disputants who are worsted in argument.

There has been more than one sign of late of this policy of carrying motions by methods equivalent to snatching. We may admire the skill of the "whips" and the tactical genius of "old Parliamentary hands" in their proper sphere, as illustrations of the "slimness" that wins success in political strife as in warfare. But the mere outwitting of opponents is surely out of place in the management of an Association whose aim should be the good of the commonweal by the furtherance of science and the defence of the interests of a profession which is composed of gentlemen. It is scarcely likely that a Charter asked for by a petition in which the names of so many leading members of the Association are conspicuous by their absence will be granted; and a refusal will be a public humiliation that will go far to nullify the influence of the Association with the profession, and its power of advancing the welfare of the public. The responsibility for this must lie on those who have shown such ill-considered haste in presenting the petition. They may have the letter of the law on their side; but abundant evidence has been forthcoming that they have not acted in accordance with its spirit.—I am, etc.,

Cardiff, Jan. 11th.

J. LYNN THOMAS.

SIR.—Surely Dr. Major Greenwood, in his letter published on January 9th, puts a very strained construction upon By-law 7. It does not seem to require any explanation to the ordinary mind that the clause he quotes, "The management of the affairs of each Branch shall be vested in a Branch Council," is not the same thing as if the clause had said that the Branch Council shall under no circumstances concern itself with anything that affects the rights and privileges of the members of the Branch. But I should like to ask, What can be more clearly, more decidedly, and more properly the affair of each Branch than anything that affects the rights of its members, or which affects the Association as a whole, of which the Branch is an integral part? To give effect to such ideas as are contained in Dr. Major Greenwood's letter would be to muzzle, as some would like to do, the individual member, and to make the Representatives our absolute dictators.

I cannot think that such a result would be to the advantage of the profession or of the Association, nor am I

alone in these views, as the following excellent and wise quotations will show:

I hope that every member of our Association will give the best attention to Dr. Walker's able letter. . . . From my own experience I can say that Representatives in the metropolitan area are elected much in the way he describes. . . . so that it must be obvious that the true representative value of our present Representative Body must be of a very meagre character. . . .

I cannot help thinking that if the present intentions of the Representative Body become stereotyped in a Royal Charter, the last stage of the Association will be worse than the first. . . . If, however, the Representative Body in its present shape becomes the sole authority, our fate will then be in the hands of a somewhat larger clique, little more truly representative of the whole Association than was the smaller one of the past, and there will be no Council with the power of shielding us in any way.

It is always well to verify one's references, so let me say that the above quotations are taken from a letter on the Referendum published in the *JOURNAL* of November 2nd, 1907, and that it appears over the signature of "Major Greenwood."—I am, etc.,

Edinburgh, Jan. 10th.

R. MCKENZIE JOHNSTON.

ABDOMINAL EMERGENCIES.
